# Hu-Tucker Binary Comparison Search Trees

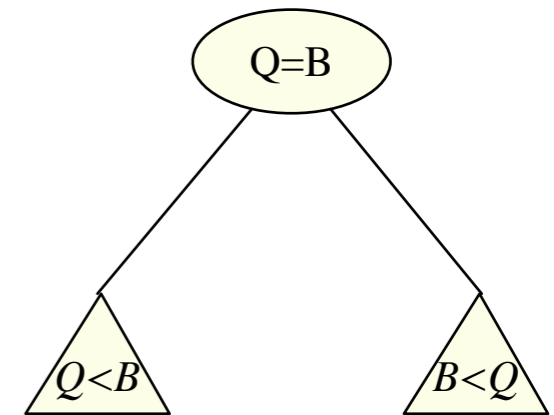

# Hu-Tucker Binary Comparison Search Trees

- Knuth constructed *optimal binary search trees*

# Hu-Tucker Binary Comparison Search Trees

- Knuth constructed *optimal binary search trees*
- Trees structure was *binary* but nodes used *ternary* comparisons. Each node needed two binary comparisons to implement the search

# Hu-Tucker Binary Comparison Search Trees

- Knuth constructed *optimal binary search trees*
- Trees structure was *binary* but nodes used *ternary* comparisons. Each node needed two binary comparisons to implement the search
- In a *binary **comparison** search tree*, each internal node performs only one comparison. Searches all terminate at leaves.
- First such trees constructed by Hu-Tucker, also in 1971.  $O(n \log n)$

# Hu-Tucker Binary Comparison Search Trees

# Hu-Tucker Binary Comparison Search Trees

# Hu-Tucker Binary Comparison Search Trees

- Hu Tucker (1971) & Garsia-Wachs (1977)
- Assumes all searches are successful; no failures allowed.  
Input is only  $\beta_1, \beta_2, \dots, \beta_n$ , with no  $\alpha_i$ s.

# Hu-Tucker Binary Comparison Search Trees

- Hu Tucker (1971) & Garsia-Wachs (1977)
- Assumes all searches are successful; no failures allowed.  
Input is only  $\beta_1, \beta_2, \dots, \beta_n$ , with no  $\alpha_i$ s.
- Internal nodes are  $<$  comparisons.  
Searches all terminate at leaves

# Hu-Tucker Binary Comparison Search Trees

- Hu Tucker (1971) & Garsia-Wachs (1977)
- Assumes all searches are successful; no failures allowed.  
Input is only  $\beta_1, \beta_2, \dots, \beta_n$ , with no  $\alpha_i$ s.
- Internal nodes are  $<$  comparisons.  
Searches all terminate at leaves
- Problem is to find tree with *minimum weighted (average) external path length*

# Hu-Tucker Binary Comparison Search Trees

- Hu Tucker (1971) & Garsia-Wachs (1977)
- Assumes all searches are successful; no failures allowed.  
Input is only  $\beta_1, \beta_2, \dots, \beta_n$ , with no  $\alpha_i$ s.
- Internal nodes are  $<$  comparisons.  
Searches all terminate at leaves
- Problem is to find tree with *minimum weighted (average) external path length*
- $O(n \log n)$  algorithm

# Adding Equality Comparisons

## Adding Equality Comparisons

The Knuth trees use three-way comparisons at each node.

These are implemented in modern machines using two two-way comparisons (one  $<$  and one  $=$ ).

Hu-Tucker trees use only one two-way comparison (a  $<$ ) at each node.

## Adding Equality Comparisons

The Knuth trees use three-way comparisons at each node.

These are implemented in modern machines using two two-way comparisons (one  $<$  and one  $=$ ).

Hu-Tucker trees use only one two-way comparison (a  $<$ ) at each node.

***. . . machines that cannot make three-way comparisons at once. . . will have to make two comparisons. . . it may well be best to have a binary tree whose internal nodes specify either an equality test or a less-than test but not both.***

## Adding Equality Comparisons

The Knuth trees use three-way comparisons at each node.

These are implemented in modern machines using two two-way comparisons (one  $<$  and one  $=$ ).

Hu-Tucker trees use only one two-way comparison (a  $<$ ) at each node.

***. . . machines that cannot make three-way comparisons at once. . . will have to make two comparisons. . . it may well be best to have a binary tree whose internal nodes specify either an equality test or a less-than test but not both.***

# Adding Equality Comparisons: AKKL[2001]

# Adding Equality Comparisons: AKKL[2001]

Hu-Tucker Tree

AKKL Tree

- AKKL trees are min cost trees with more power.  
instead of being restricted to be  $<$ , comparisons can be  $=$  OR  $<$

# Adding Equality Comparisons: AKKL[2001]

Hu-Tucker Tree

AKKL Tree

- AKKL trees are min cost trees with more power.  
instead of being restricted to be  $<$ , comparisons can be  $=$  OR  $<$
- AKKL trees include HT Trees

# Adding Equality Comparisons: AKKL[2001]

Hu-Tucker Tree

AKKL Tree

- AKKL trees are min cost trees with more power.  
instead of being restricted to be  $<$ , comparisons can be  $=$  OR  $<$
- AKKL trees include HT Trees
- AKKL trees can be cheaper than HT Trees if some  $\beta_i$  much *larger* than others

# Adding Equality Comparisons: AKKL[2001]

Hu-Tucker Tree

AKKL Tree

- AKKL trees are min cost trees with more power.  
instead of being restricted to be  $<$ , comparisons can be  $=$  OR  $<$
- AKKL trees include HT Trees
- AKKL trees can be cheaper than HT Trees if some  $\beta_i$  much *larger* than others
- AKKL trees more difficult to construct

# Adding Equality Comparisons: AKKL[2001]

# Adding Equality Comparisons: AKKL[2001]

- Anderson, Kannan, Karloff, Ladner [2002] extended Hu-Tucker by allowing = comparisons. AKKL find min-cost tree when the  $n-1$  internal node comparisons are allowed to be in  $\{=, <\}$ .

# Adding Equality Comparisons: AKKL[2001]

- Anderson, Kannan, Karloff, Ladner [2002] extended Hu-Tucker by allowing = comparisons. AKKL find min-cost tree when the  $n-1$  internal node comparisons are allowed to be in  $\{=, <\}$ .
- Useful when some  $\beta_i$  are very large (relatively)

# Adding Equality Comparisons: AKKL[2001]

- Anderson, Kannan, Karloff, Ladner [2002] extended Hu-Tucker by allowing = comparisons. AKKL find min-cost tree when the  $n-1$  internal node comparisons are allowed to be in  $\{=, <\}$ .
- Useful when some  $\beta_i$  are very large (relatively)
- AKKL algorithm runs in  $O(n^4)$  time.

# Adding Equality Comparisons: AKKL[2001]

- Anderson, Kannan, Karloff, Ladner [2002] extended Hu-Tucker by allowing = comparisons. AKKL find min-cost tree when the  $n-1$  internal node comparisons are allowed to be in  $\{=, <\}$ .
- Useful when some  $\beta_i$  are very large (relatively)
- AKKL algorithm runs in  $O(n^4)$  time.
  - AKKL note this improves running time of  $O(n^5)$  claimed by Spuler [1994] in his thesis

# Adding Equality Comparisons: AKKL[2001]

- Anderson, Kannan, Karloff, Ladner [2002] extended Hu-Tucker by allowing  $=$  comparisons. AKKL find min-cost tree when the  $n-1$  internal node comparisons are allowed to be in  $\{=, <\}$ .
- Useful when some  $\beta_i$  are very large (relatively)
- AKKL algorithm runs in  $O(n^4)$  time.
  - AKKL note this improves running time of  $O(n^5)$  claimed by Spuler [1994] in his thesis
  - Spuler only states  $O(n^5)$  algorithm but doesn't prove that it produces optimal tree, so AKKL is really first polynomial time algorithm

# Adding Equality Comparisons: AKKL[2001]

- Anderson, Kannan, Karloff, Ladner [2002] extended Hu-Tucker by allowing = comparisons. AKKL find min-cost tree when the  $n-1$  internal node comparisons are allowed to be in  $\{=, <\}$ .
- Useful when some  $\beta_i$  are very large (relatively)
- AKKL algorithm runs in  $O(n^4)$  time.
  - AKKL note this improves running time of  $O(n^5)$  claimed by Spuler [1994] in his thesis
  - Spuler only states  $O(n^5)$  algorithm but doesn't prove that it produces optimal tree, so AKKL is really first polynomial time algorithm
- Reason problem is difficult is that equality nodes can create *holes* in ranges. This could dramatically (exponentially?) increase search space, destroying DP approach

# Adding Equality Comparisons: AKKL[2001]

- Anderson, Kannan, Karloff, Ladner [2002] extended Hu-Tucker by allowing = comparisons. AKKL find min-cost tree when the  $n-1$  internal node comparisons are allowed to be in  $\{=, <\}$ .
- Useful when some  $\beta_i$  are very large (relatively)
- AKKL algorithm runs in  $O(n^4)$  time.
  - AKKL note this improves running time of  $O(n^5)$  claimed by Spuler [1994] in his thesis
  - Spuler only states  $O(n^5)$  algorithm but doesn't prove that it produces optimal tree, so AKKL is really first polynomial time algorithm
- Reason problem is difficult is that equality nodes can create *holes* in ranges. This could dramatically (exponentially?) increase search space, destroying DP approach
  - AKKL show that if equality comparison exists, then it is always largest probability in range. Allows recovering DP approach with ranges of description size  $O(n^3)$  (compared to Knuth's  $O(n^2)$ )

# Adding Equality Comparisons: AKKL[2001]

Hu-Tucker Tree

AKKL Tree

- *Comment 1 : Other problem in AKKL is how to deal with repeated weights  
This was hardest part.*
- *Comment 2: Both Hu-Tucker and AKKL only work when failures don't occur.  
I.e., only  $\beta_i$  are allowed and not  $\alpha_i$ .*

# So Far + Obvious Open Problem

## So Far + Obvious Open Problem

- Optimal Binary Search Trees
  - Input:  $\beta_i = \Pr(Q = K_i)$ ;  $\alpha_i = \Pr(K_{i-1} < Q < K_i)$
  - $O(n^2)$  Knuth
- Optimal Binary Comparison Search Trees
  - Input:  $\beta_i = \Pr(Q = K_i)$ ; failures not allowed
  - $C = \{<\}$ :  $O(n \log n)$  Hu-Tucker & Garsia-Wachs
  - $C = \{=, <\}$ :  $O(n^4)$  AKKL

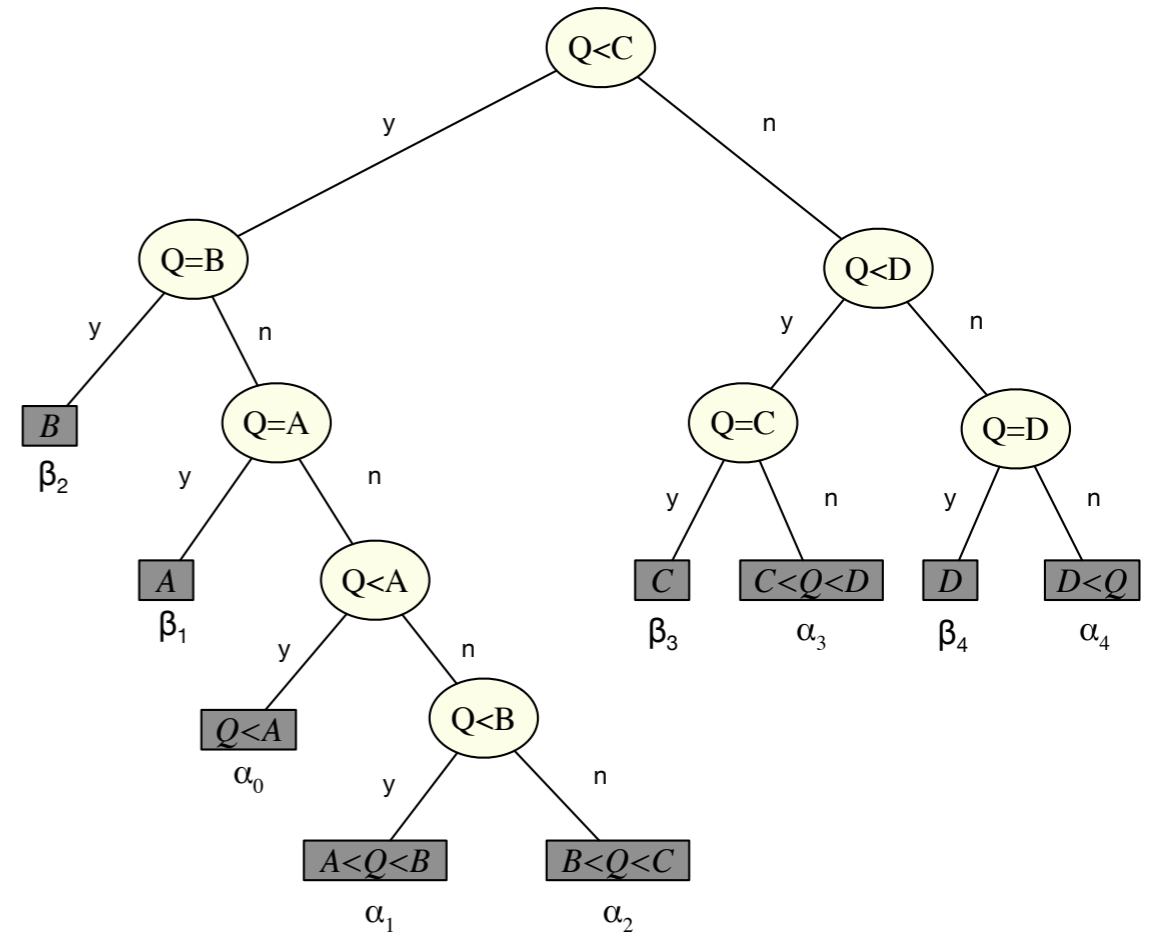

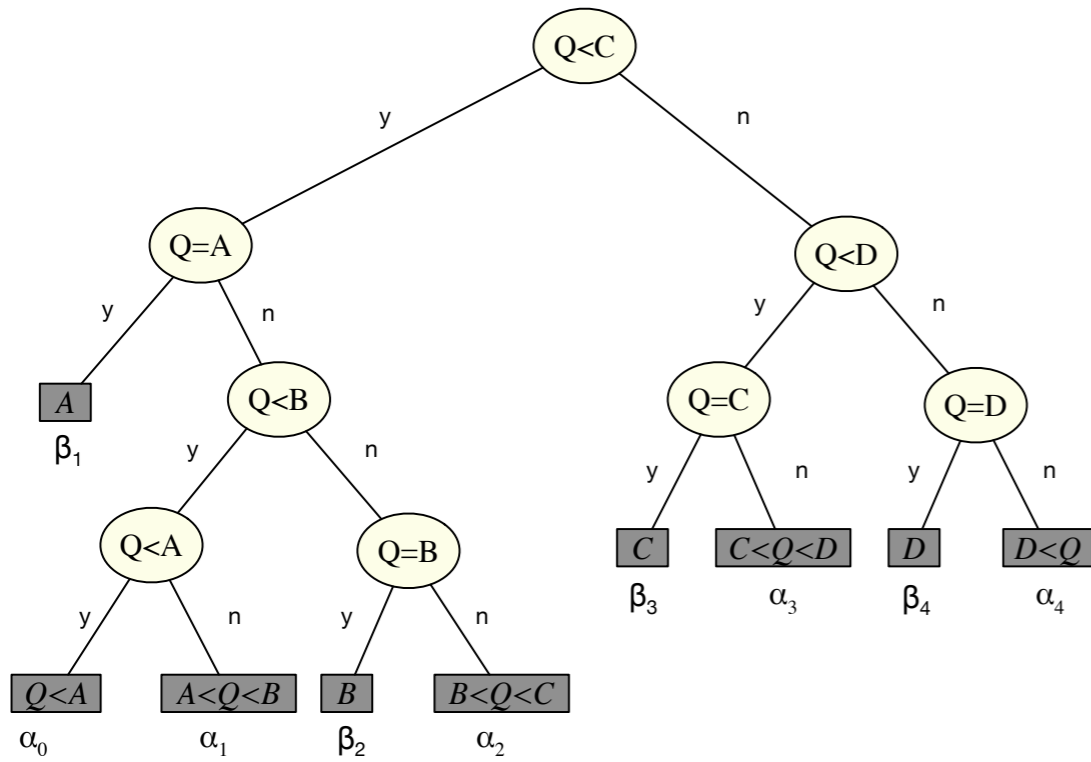

## So Far + Obvious Open Problem

- Optimal Binary Search Trees
  - Input:  $\beta_i = \Pr(Q = K_i)$ ;  $\alpha_i = \Pr(K_{i-1} < Q < K_i)$
  - $O(n^2)$  Knuth
- Optimal Binary Comparison Search Trees
  - Input:  $\beta_i = \Pr(Q = K_i)$ ; failures not allowed
  - $C = \{<\}$ :  $O(n \log n)$  Hu-Tucker & Garsia-Wachs
  - $C = \{=, <\}$ :  $O(n^4)$  AKKL
- Obvious Questions
  - Can we build OBCSTs that allow failures?
    - If yes, for which sets of comparisons?
  - Answer is yes, (for all sets of comparisons) but first need to define problem models

# BCSTs with Failure Probabilities

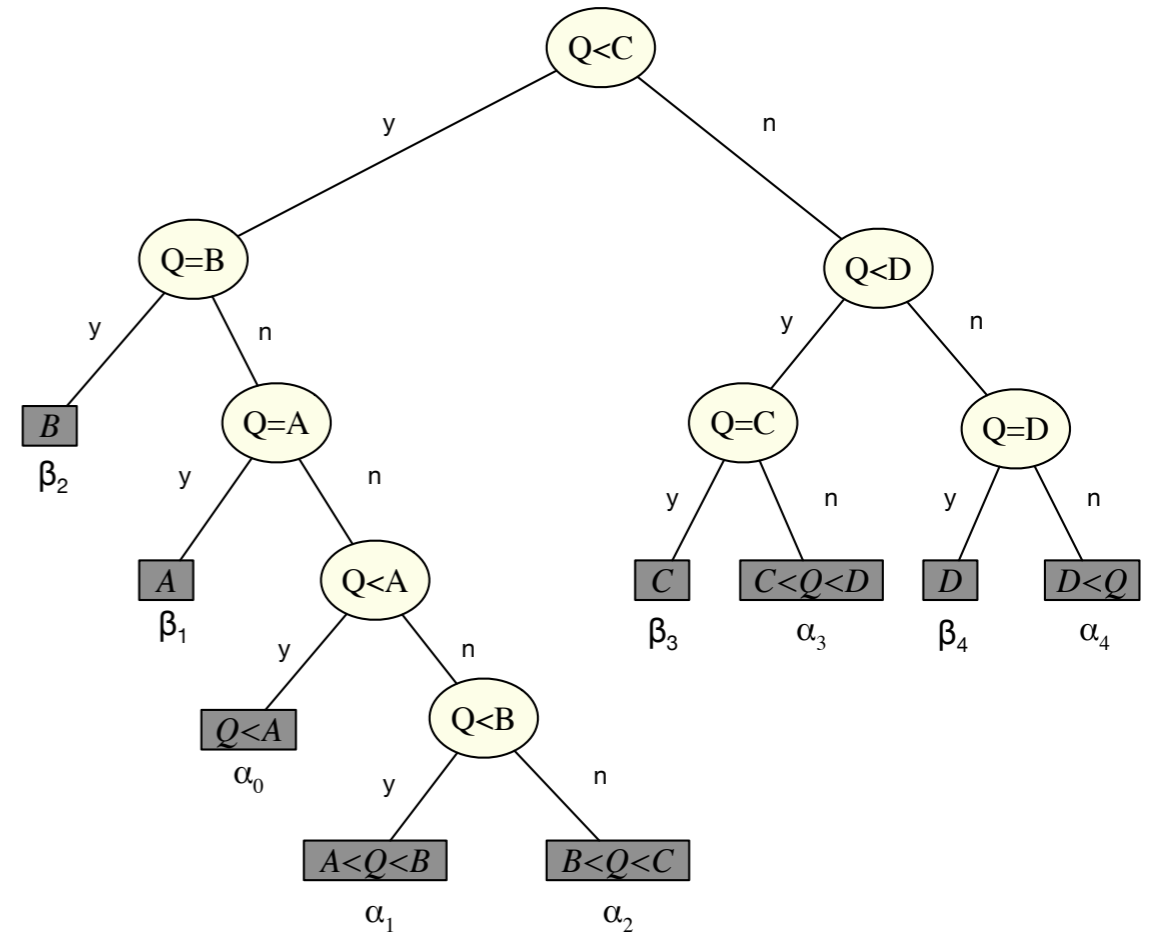

# BCSTs with Failure Probabilities

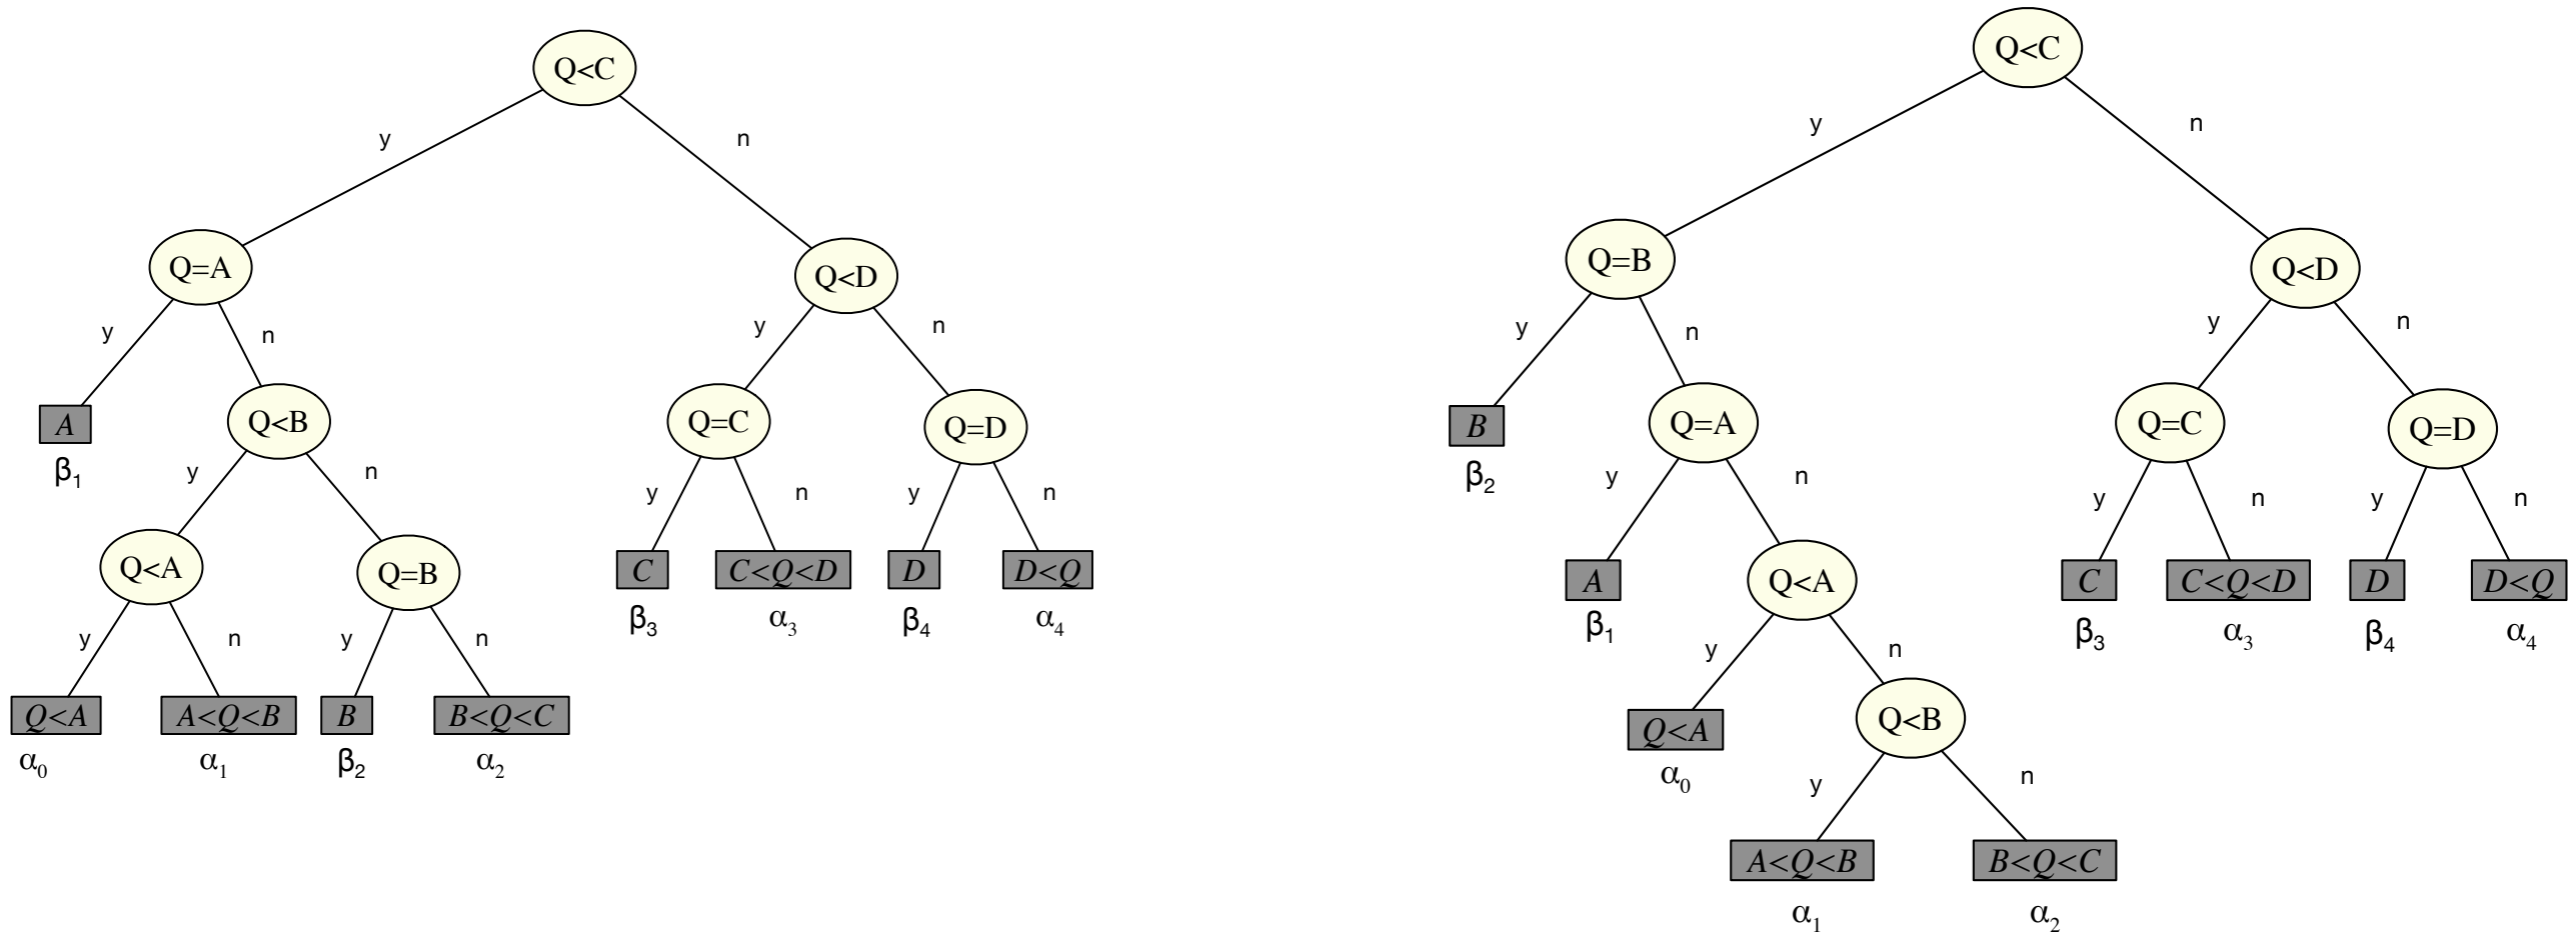

- Allows Failures ( $\beta_i$  and  $\alpha_i$ ).
- Call this *complete input*. HT has *restricted input*.

# BCSTs with Failure Probabilities

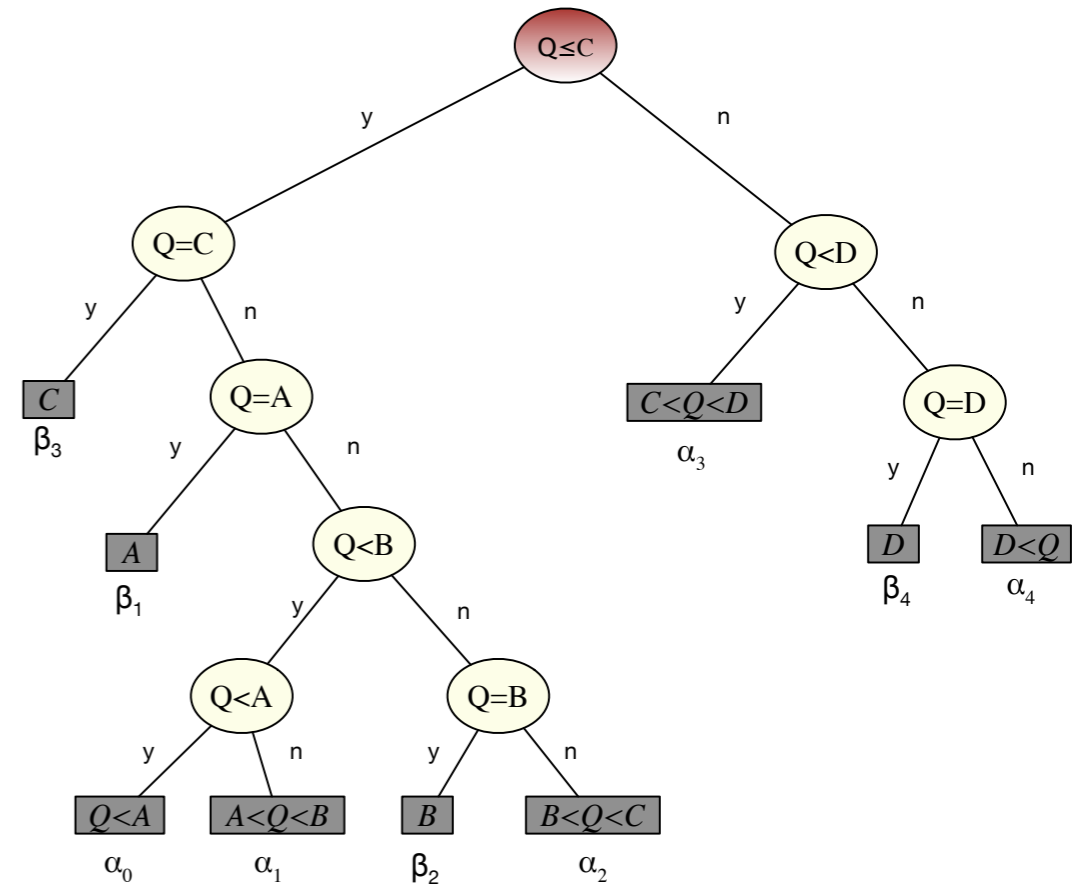

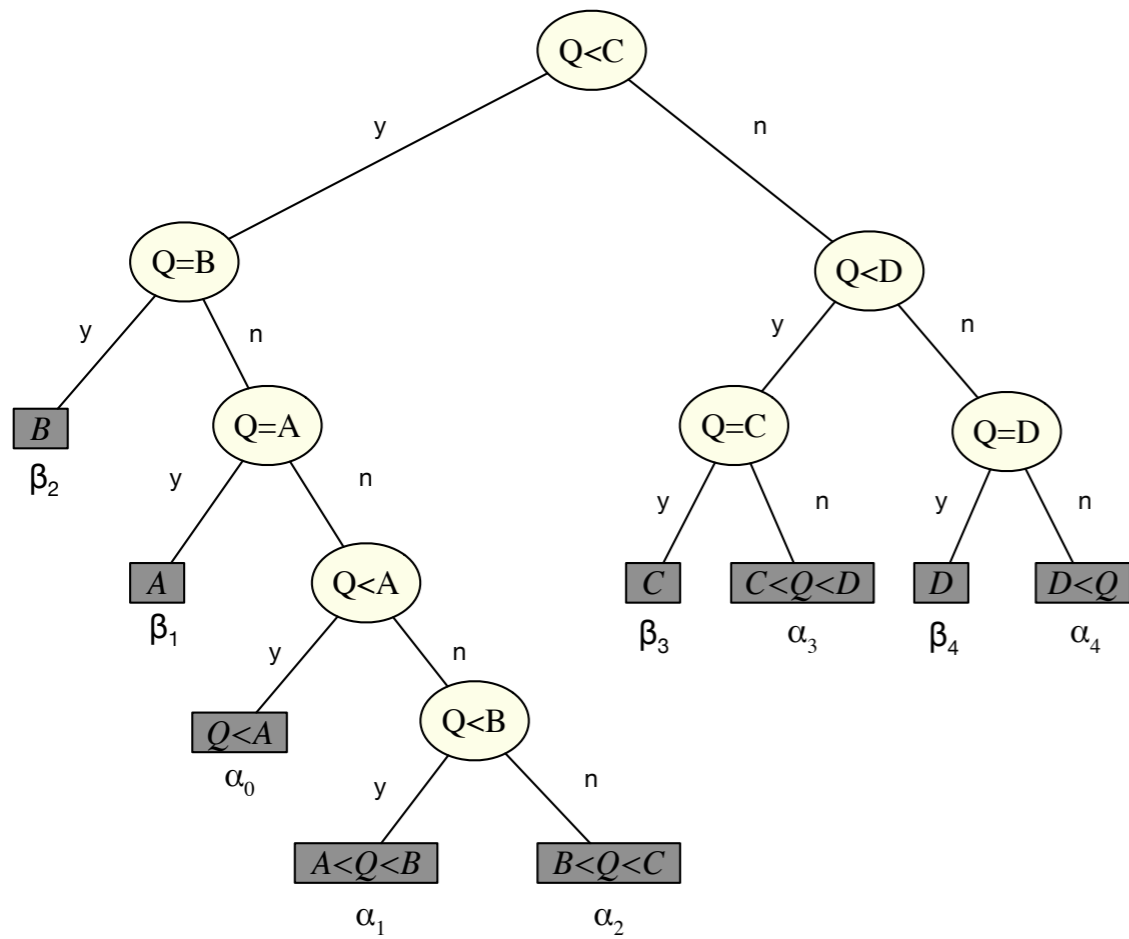

- Allows Failures ( $\beta_i$  and  $\alpha_i$ ).
  - Call this *complete input*. HT has *restricted input*.
- Tree for  $n$  keys has  $2n+1$  leaves

# BCSTs with Failure Probabilities

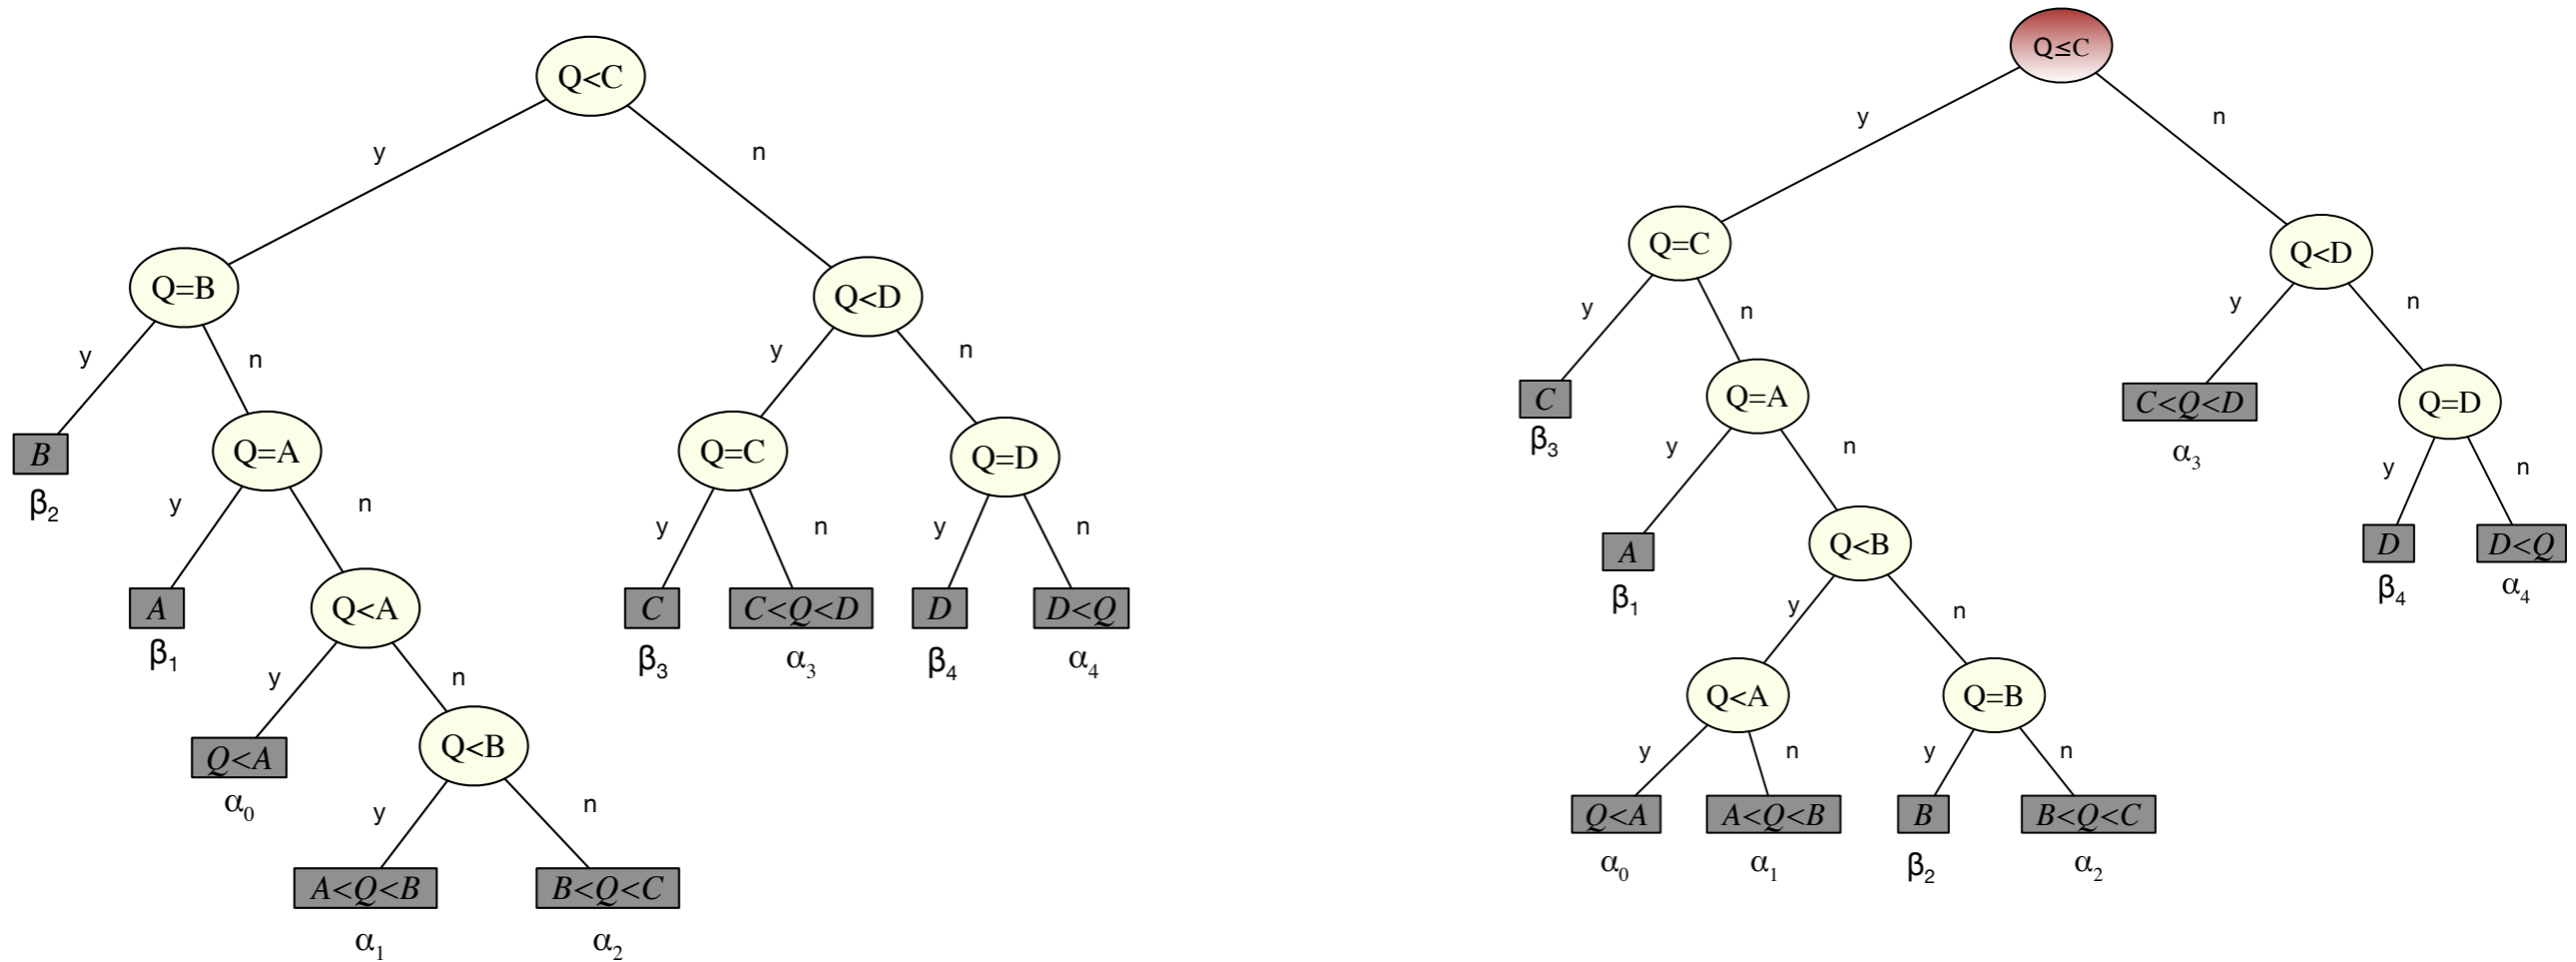

- Allows Failures ( $\beta_i$  and  $\alpha_i$ ).
  - Call this *complete input*. HT has *restricted input*.
- Tree for  $n$  keys has  $2n+1$  leaves
- Distinguishing between  $Q == K_i$  and  $K_i < Q < K_{i+1}$  always requires querying ( $Q = K_i$ )

# Using Different Types of Comparisons

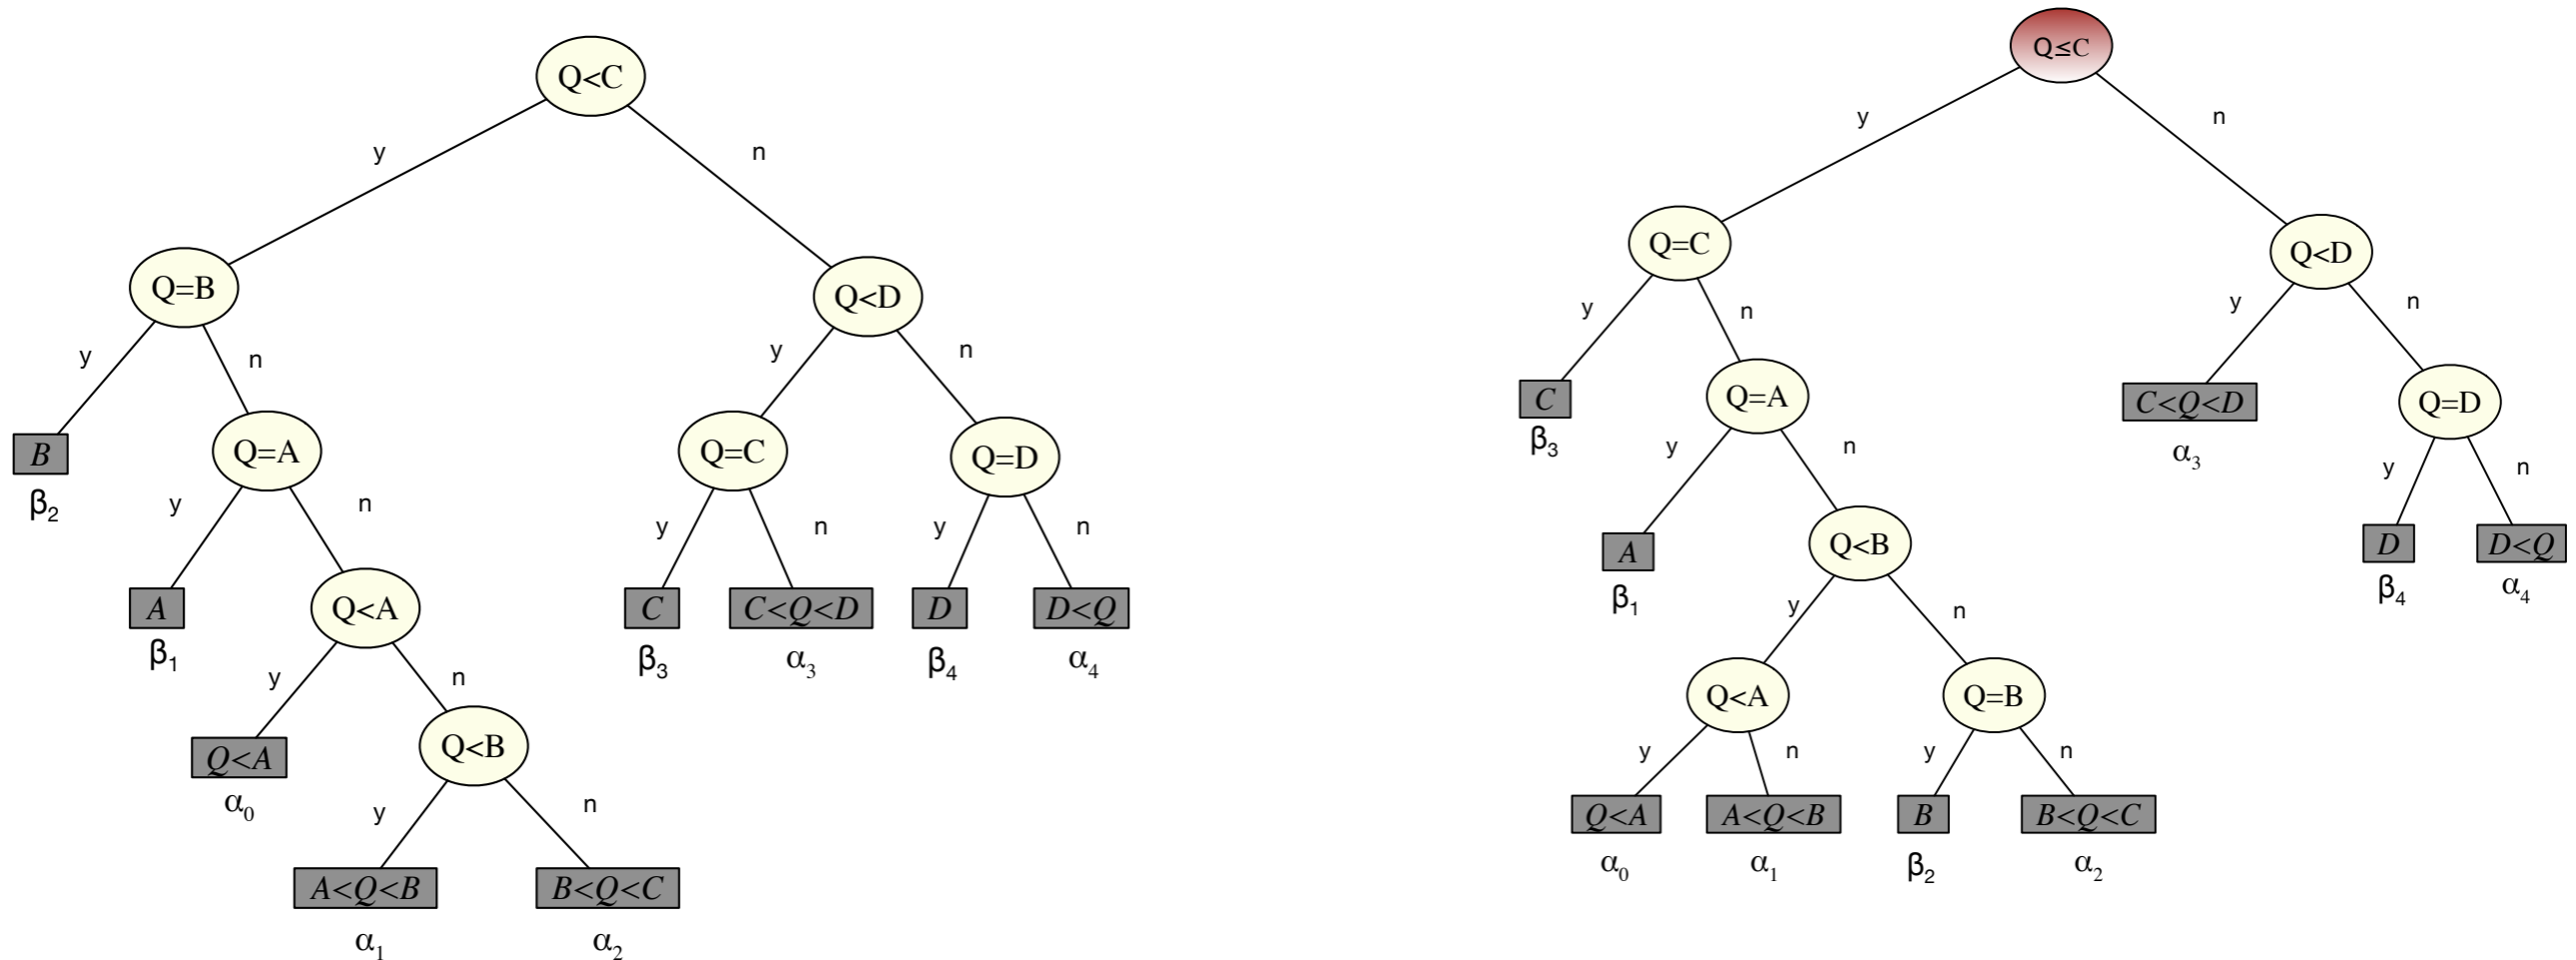

# Using Different Types of Comparisons

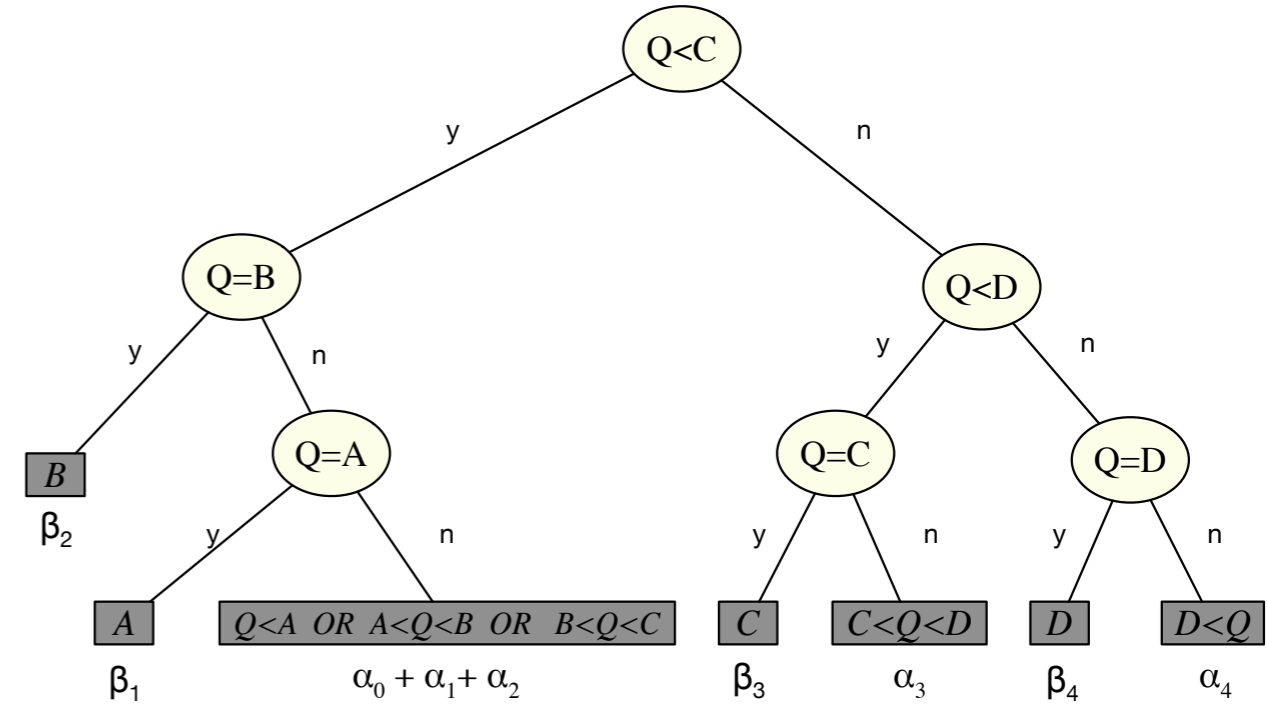

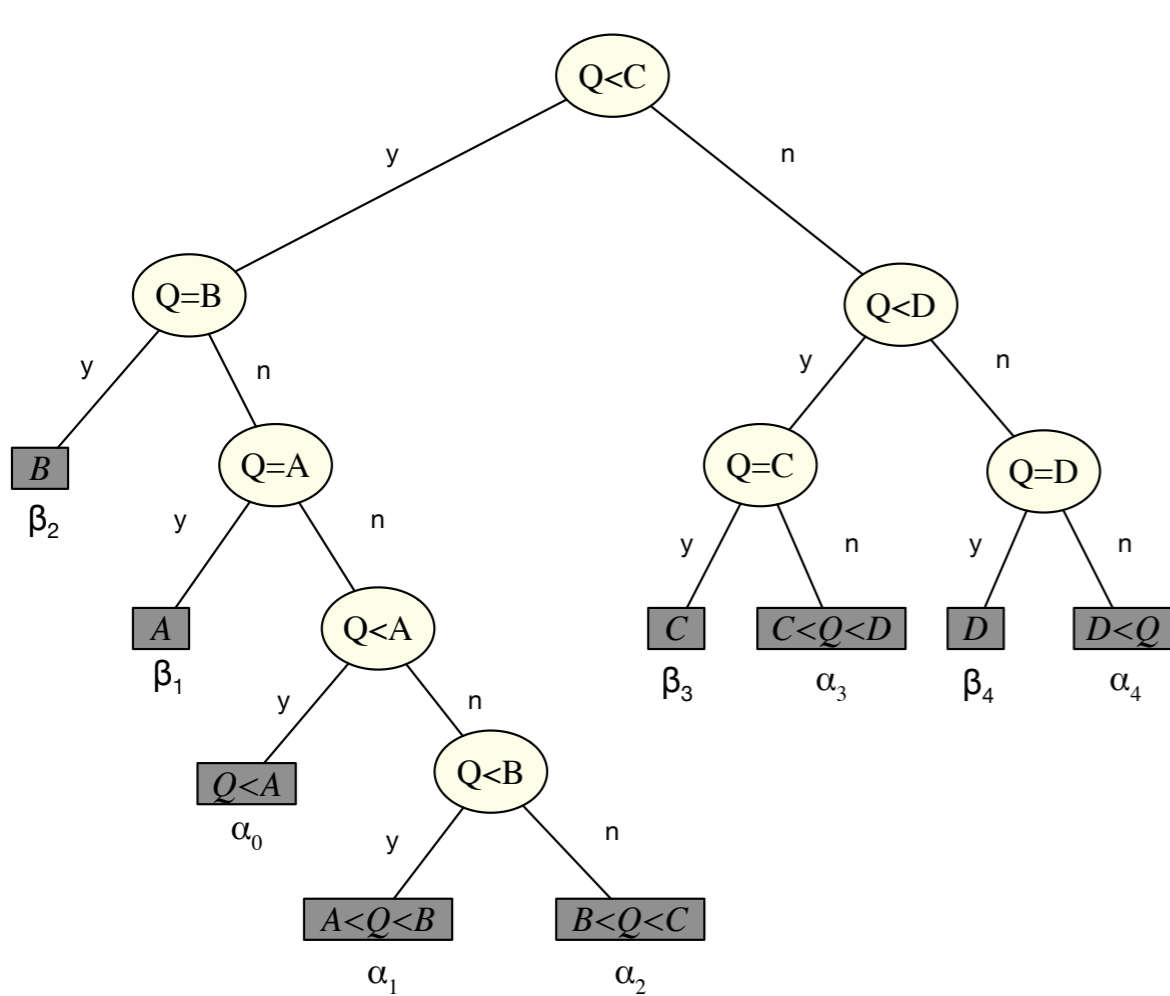

- Left Tree uses  $\{<, =\}$ . Right Tree uses  $\{<, \leq, =\}$ 
  - Minimum cost BCST is minimum taken over all trees using given set of comparisons  $C$ , e.g.,  $C = \{<, =\}$  or  $C = \{<, \leq, =\}$

# Using Different Types of Comparisons

- Left Tree uses  $\{<, =\}$ . Right Tree uses  $\{<, \leq, =\}$ 
  - Minimum cost BCST is minimum taken over all trees using given set of comparisons  $C$ , e.g.,  $C=\{<, =\}$  or  $C=\{<, \leq, =\}$
- $C$  is input to the problem.
  - Algorithm is different for different  $C$ s.

# How Much Information is Needed for Failure?

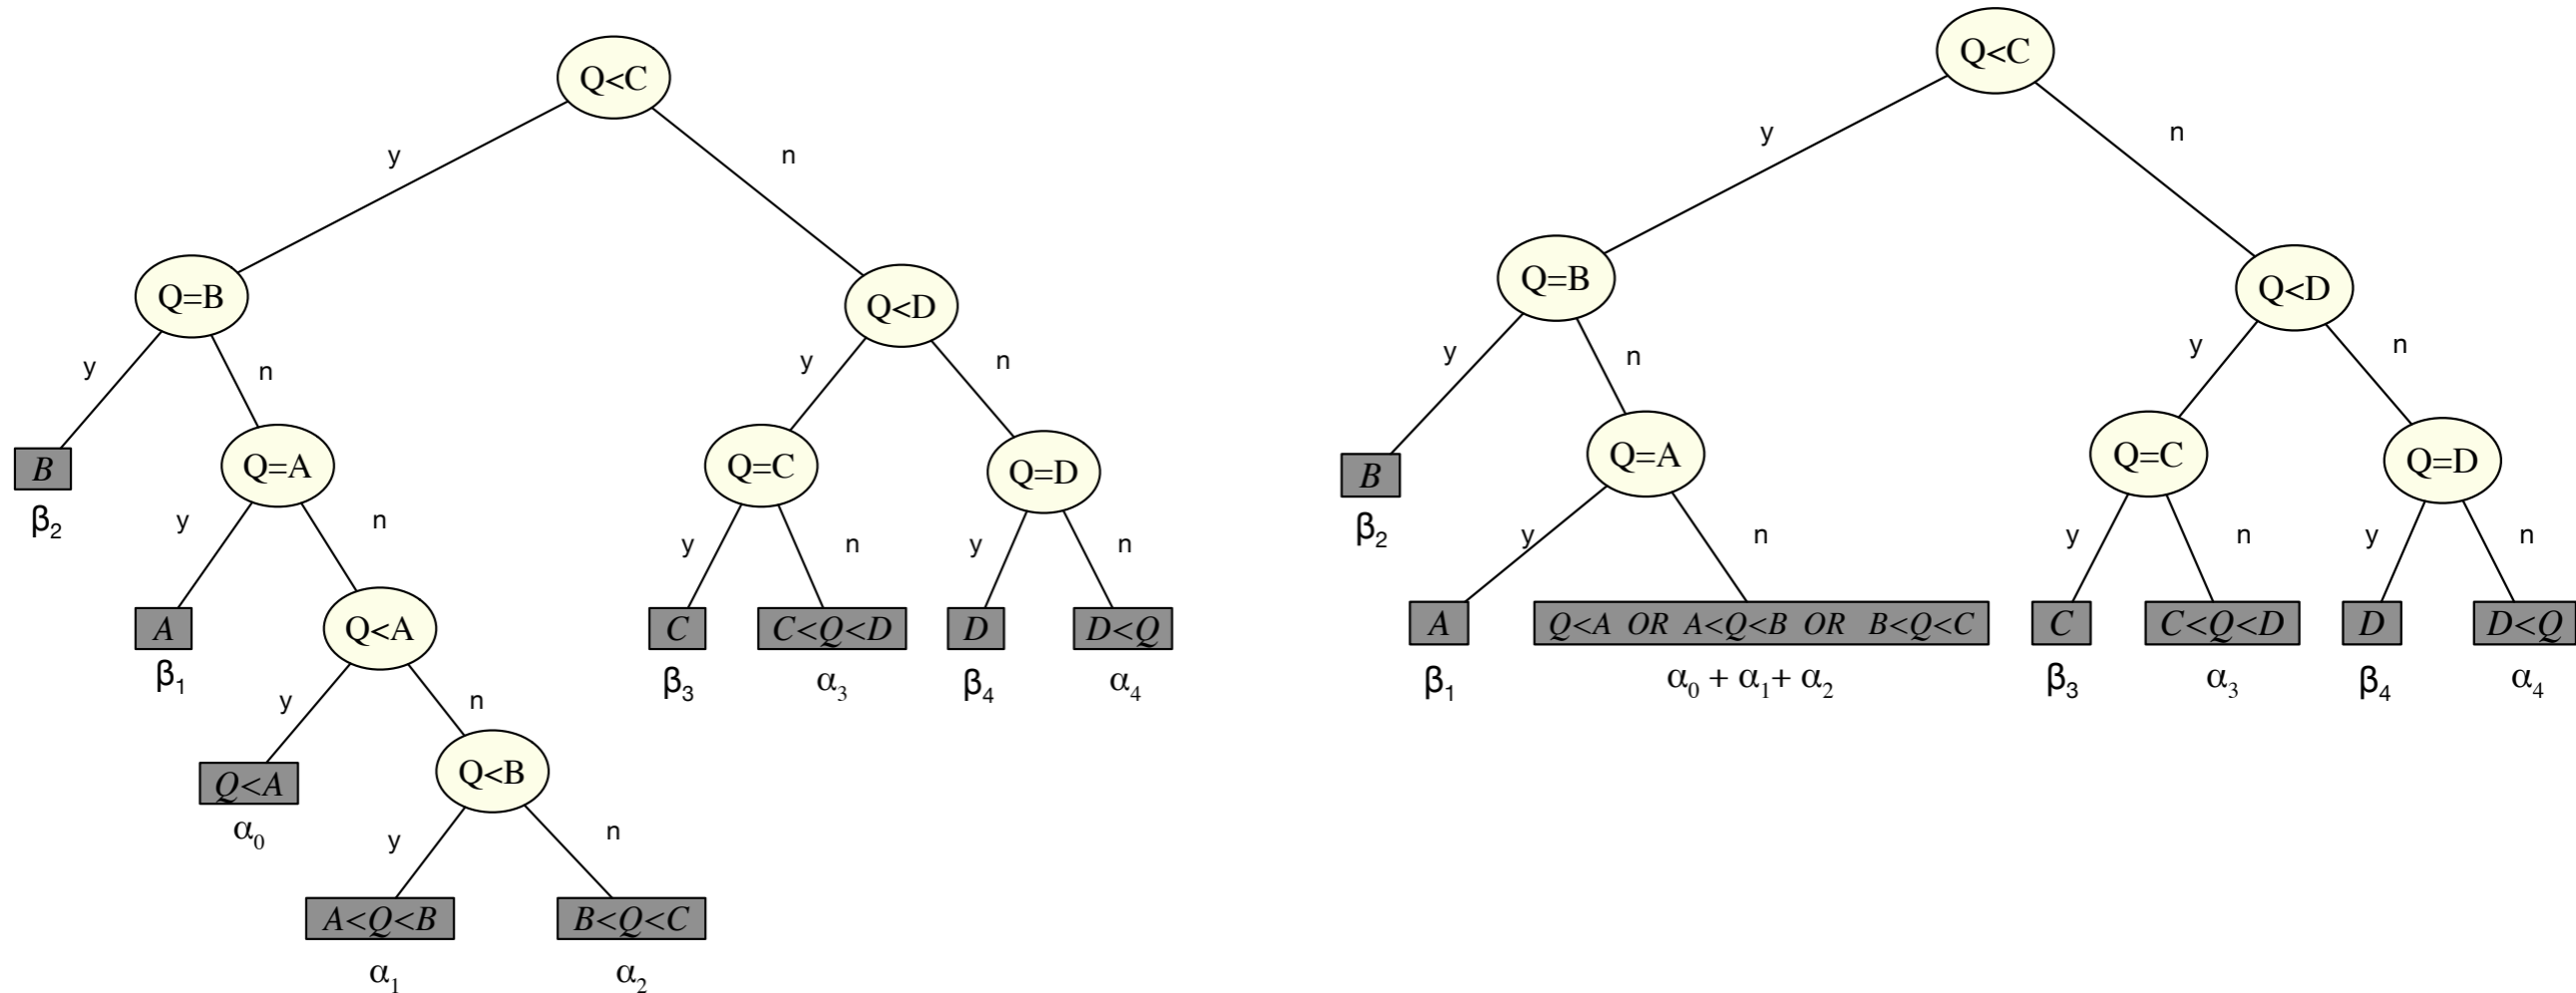

# How Much Information is Needed for Failure?

- Tree on left shows **Explicit Failure**
  - every failure leaf reports unique failure interval,  $K_i < Q < K_{i+1}$ .

# How Much Information is Needed for Failure?

- Tree on left shows **Explicit Failure**
  - every failure leaf reports unique failure interval,  $K_i < Q < K_{i+1}$ .
- Tree on right shows **Non-Explicit Failure:**
  - Failure leaves only report failure. Don't need to specify exact interval. Leaf can be concatenation of successive failure intervals .

# New Algorithms: OBCSTs with Failures

Permitted Comparisons	Failure Type	Time	Comments
$\mathcal{C} = \{=\}$	Explicit	—	Can not occur
	Non-Explicit	$O(n \log n)$	Trivial. Similar to Linked List
$\mathcal{C} = \{<, \leq\}$	Explicit	$O(n \log n)$	$O(n)$ Reduction to Hu-Tucker
	Non-Explicit	—	Can not occur
$\mathcal{C} = \{=, <\}, \mathcal{C} = \{=, \leq\}$	Explicit	$O(n^4)$	Follows from Main Lemma
	Non-Explicit	$O(n^4)$	”
$\mathcal{C} = \{=, <, \leq\}$	Explicit	$O(n^4)$	”
	Non-Explicit	$O(n^4)$	”

- DP Algorithms for last 4 cases are very similar
- Differ slightly in
  - Design of Recurrence Relations
    - $\{=, <\}$  and  $\{=, <, \leq\}$  yield slightly different recurrences
  - Initial conditions
    - Explicit and Non-Explicit Failures force different I.C.s

# Dynamic programming for OBCSTs

# Dynamic programming for OBCSTs

- Let  $T$  be an OBCST for  $[i, j: h)$
- $T$  Has two possible structures

# Dynamic programming for OBCSTs

- Let  $T$  be an OBCST for  $[i, j: h)$
- $T$  Has two possible structures

1. Root is a  $(Q=K_k)$

# Dynamic programming for OBCSTs

- Let  $T$  be an OBCST for  $[i, j: h)$
- $T$  Has two possible structures

1. Root is a  $(Q=K_k)$

2. Root is a  $(Q < K_k)$

# Dynamic programming for OBCSTs

1. Root of  $\text{OPT}(i,j:h)$  is a  $(Q=K_k)$

# Dynamic programming for OBCSTs

## 1. Root of $\text{OPT}(i,j:h)$ is a $(Q=K_k)$

- $K_k$  must be largest key weight in  $[i,j:h)$  which is  $(h+1)^{\text{st}}$  largest key weight in  $[i,j)$
- Right subtree missing  $h+1$  largest weights in  $[i,j)$  so right subtree is  $\text{OPT}(i,j:h+1)$

# Dynamic programming for OBCSTs

## 1. Root of $OPT(i,j: h)$ is a $(Q=K_k)$

- $K_k$  must be largest key weight in  $[i,j: h)$  which is  $(h+1)^{st}$  largest key weight in  $[i,j)$
- Right subtree missing  $h+1$  largest weights in  $[i,j)$  so right subtree is  $OPT(i,j: h+1)$

Cost of full tree is sum of

- cost of left subtree  $0$
- cost of right subtree  $OPT(i,j: h+1)$
- Total weight of left + right subtree  $W_{i,j:h}$   
where  $W_{i,j:h} = \text{sum of all } \beta_i, \alpha_i \text{ in } (i,j: h)$

# Dynamic programming for OBCSTs

## 1. Root of $OPT(i,j:h)$ is a $(Q=K_k)$

- $K_k$  must be largest key weight in  $[i,j:h)$  which is  $(h+1)^{st}$  largest key weight in  $[i,j)$
- Right subtree missing  $h+1$  largest weights in  $[i,j)$  so right subtree is  $OPT(i,j:h+1)$

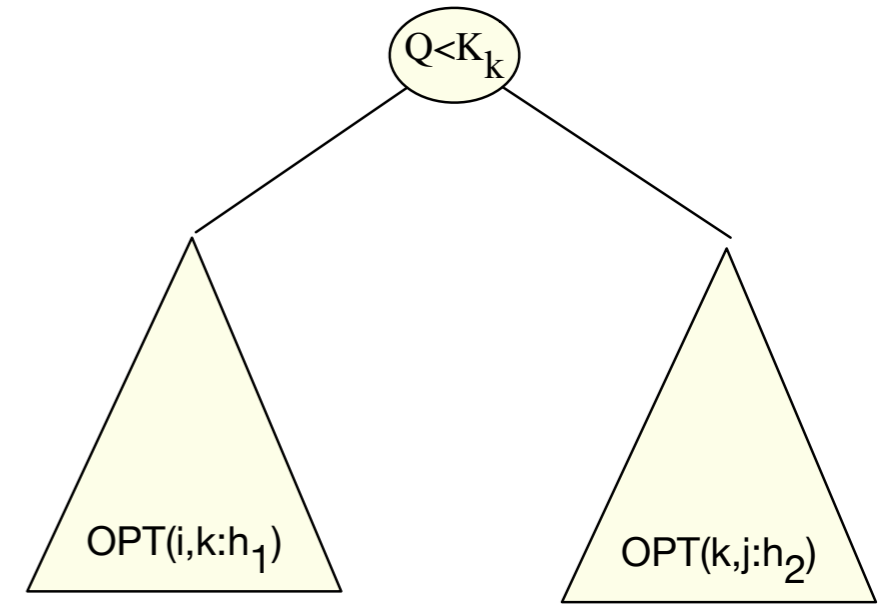

Cost of full tree is sum of

- cost of left subtree  $0$
- cost of right subtree  $OPT(i,j:h+1)$
- Total weight of left + right subtree  $W_{i,j:h}$  where  $W_{i,j:h} = \text{sum of all } \beta_i, \alpha_i \text{ in } (i,j:h)$

$$EQ(i,j:h) = W_{i,j:h} + OPT(i,j:h+1)$$

# Dynamic programming for OBCSTs

2. Root of  $\text{OPT}(i,j:h)$  is a  $(Q < K_k)$

# Dynamic programming for OBCSTs

## 2. Root of $\text{OPT}(i,j:h)$ is a $(Q < K_k)$

- Range is split into  $<k$  and  $\geq k$
- $h$  holes (largest keys) in  $[i,j)$  are split, with  $h_1(k)$  on left and  $h_2(k) = h - h_1(k)$  on right

# Dynamic programming for OBCSTs

## 2. Root of $\text{OPT}(i,j:h)$ is a $(Q < K_k)$

- Range is split into  $<k$  and  $\geq k$
- $h$  holes (largest keys) in  $[i,j)$  are split, with  $h_1(k)$  on left and  $h_2(k) = h - h_1(k)$  on right
- $h_1(k)$  keys must be heaviest in  $[i,k)$   
 $h_2(k)$  keys must be heaviest in  $[k,j)$
- So left and right subtrees are OBCSTs for  $[i,k:h_1(k))$  and  $[k,j:h_2(k))$

# Dynamic programming for OBCSTs

## 2. Root of $\text{OPT}(i,j:h)$ is a $(Q < K_k)$

- Range is split into  $<k$  and  $\geq k$
- $h$  holes (largest keys) in  $[i,j)$  are split, with  $h_1(k)$  on left and  $h_2(k) = h - h_1(k)$  on right
- $h_1(k)$  keys must be heaviest in  $[i,k)$   
 $h_2(k)$  keys must be heaviest in  $[k,j)$
- So left and right subtrees are OBCSTs for  $[i,k: h_1(k))$  and  $[k,j: h_2(k))$
- Cost of tree is  $W_{i,j:h} + \text{OPT}(i,k: h_1(k)) + \text{OPT}(k,j: h_2(k))$

# Dynamic programming for OBCSTs

## 2. Root of $OPT(i,j:h)$ is a $(Q < K_k)$

- Range is split into  $<k$  and  $\geq k$
- $h$  holes (largest keys) in  $[i,j)$  are split, with  $h_1(k)$  on left and  $h_2(k) = h - h_1(k)$  on right
- $h_1(k)$  keys must be heaviest in  $[i,k)$   
 $h_2(k)$  keys must be heaviest in  $[k,j)$
- So left and right subtrees are OBCSTs for  $[i,k: h_1(k))$  and  $[k,j: h_2(k))$
- Cost of tree is  $W_{i,j:h} + OPT(i,k: h_1(k)) + OPT(k,j: h_2(k))$

Don't know what  $k$  is, so minimize over all possible  $k$

$$SPLIT(i, j : h) = \min_{i < k < j} \{ W_{i,j:h} + OPT(i, k : h_1(k)) + OPT(k, j : h_2(k)) \}$$

# Dynamic programming for OBCSTs

## Dynamic programming for OBCSTs

$\text{OPT}(i,j: h)$  has two possible structures

# Dynamic programming for OBCSTs

$OPT(i,j:h)$  has two possible structures

1. Root is a  $(Q=K_k)$

2. Root is a  $(Q < K_k)$

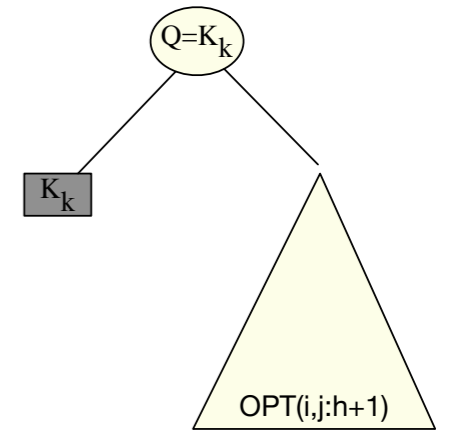

# Dynamic programming for OBCSTs

$OPT(i,j:h)$  has two possible structures

1. Root is a  $(Q=K_k)$

$$EQ(i, j : h) = W_{i,j:h} + OPT(i, j : h + 1)$$

2. Root is a  $(Q < K_k)$

$$SPLIT(i, j : h) = \min_{i < k < j} \{ W_{i,j:h} + OPT(i, k : h_1(k)) + OPT(k, j : h_2(k)) \}$$

# Dynamic programming for OBCSTs

$OPT(i,j:h)$  has two possible structures

1. Root is a  $(Q=K_k)$

$$EQ(i,j:h) = W_{i,j:h} + OPT(i,j:h+1)$$

2. Root is a  $(Q < K_k)$

$$SPLIT(i,j:h) = \min_{i < k < j} \{W_{i,j:h} + OPT(i,k:h_1(k)) + OPT(k,j:h_2(k))\}$$

This immediately implies

$$OPT(i,j:h) \geq \min (EQ(i,j:h), SPLIT(i,j:h))$$

# Dynamic programming for OBCSTs

$OPT(i,j:h)$  has two possible structures

1. Root is a  $(Q=K_k)$

$$EQ(i,j:h) = W_{i,j:h} + OPT(i,j:h+1)$$

2. Root is a  $(Q < K_k)$

$$SPLIT(i,j:h) = \min_{i < k < j} \{W_{i,j:h} + OPT(i,k:h_1(k)) + OPT(k,j:h_2(k))\}$$

This immediately implies

$$OPT(i,j:h) \geq \min (EQ(i,j:h), SPLIT(i,j:h))$$

But every case seen can construct a BCST with that cost, so

$$OPT(i,j:h) = \min (EQ(i,j:h), SPLIT(i,j:h))$$

# Dynamic programming for OBCSTs

$$OPT(i, j : h) = \min (EQ(i, j : h), SPLIT(i, j : h))$$

$$EQ(i, j : h) = W_{i,j:h} + OPT(i, j : h + 1)$$

$$SPLIT(i, j : h) = \min_{i < k < j} \{W_{i,j:h} + OPT(i, k : h_1(k)) + OPT(k, j : h_2(k))\}$$

## Dynamic programming for OBCSTs

$$OPT(i, j : h) = \min (EQ(i, j : h), SPLIT(i, j : h))$$

$$EQ(i, j : h) = W_{i,j:h} + OPT(i, j : h + 1)$$

$$SPLIT(i, j : h) = \min_{i < k < j} \{W_{i,j:h} + OPT(i, k : h_1(k)) + OPT(k, j : h_2(k))\}$$

Set initial conditions for ranges  $OPT(i, i+1, *)$

# Dynamic programming for OBCSTs

$$OPT(i, j : h) = \min (EQ(i, j : h), SPLIT(i, j : h))$$

$$EQ(i, j : h) = W_{i,j:h} + OPT(i, j : h + 1)$$

$$SPLIT(i, j : h) = \min_{i < k < j} \{ W_{i,j:h} + OPT(i, k : h_1(k)) + OPT(k, j : h_2(k)) \}$$

Set initial conditions for ranges  $OPT(i, i+1, *)$

$$OPT(i, i+1, 1) = 0$$

$$\boxed{K_i < Q < K_{i+1}} \alpha_i$$

$$OPT(i, i+1, 0) = \beta_i + \alpha_i$$

# Dynamic programming for OBCSTs

$$OPT(i, j : h) = \min (EQ(i, j : h), SPLIT(i, j : h))$$

$$EQ(i, j : h) = W_{i,j:h} + OPT(i, j : h + 1)$$

$$SPLIT(i, j : h) = \min_{i < k < j} \{ W_{i,j:h} + OPT(i, k : h_1(k)) + OPT(k, j : h_2(k)) \}$$

Set initial conditions for ranges  $OPT(i, i+1, *)$

$$OPT(i, i+1, 1) = 0$$

$$\boxed{K_i < Q < K_{i+1}} \quad \alpha_i$$

$$OPT(i, i+1, 0) = \beta_i + \alpha_i$$

  - $\Rightarrow \beta'_i$  are all distinct
- Since  $\beta'_i$  are all distinct, algorithm gives correct result for  $\alpha'_i, \beta'_i$ 
  - Easy to prove that optimum tree for  $\alpha'_i, \beta'_i$  is optimum for  $\alpha_i, \beta_i$
  - $\Rightarrow$  resulting tree is optimum for original  $\alpha_i, \beta_i$

# Perturbing for Key Weight Uniqueness (I)

- Strongly used assumption  **$\beta_i$  are all distinct** to find 'weightiest' keys
  - Assumption can be removed using perturbation argument
- All values constructed/compared in algorithm are subtree costs
  - in form  $\sum a_i \alpha_i + \sum b_i \beta_i$  where  $0 \leq a_i, b_i \leq 2n$  are integral node depths
- Perturb input by setting  **$\alpha'_i = \alpha_i$  ,  $\beta'_i = \beta_i + i\epsilon$**  where  $\epsilon$  is very small
  - $\Rightarrow \beta'_i$  are all distinct
- Since  $\beta'_i$  are all distinct, algorithm gives correct result for  $\alpha'_i, \beta'_i$ 
  - Easy to prove that optimum tree for  $\alpha'_i, \beta'_i$  is optimum for  $\alpha_i, \beta_i$
  - $\Rightarrow$  resulting tree is optimum for original  $\alpha_i, \beta_i$
- In fact don't actually need to know value of  $\epsilon$

# Perturbing for Key Weight Uniqueness (II)

# Perturbing for Key Weight Uniqueness (II)

- Perturb input:  $\alpha'_i = \alpha_i$  ,  $\beta'_i = \beta_i + i\epsilon$  where  $\epsilon$  is very small
  - Need to find optimum tree for  $\alpha'_i, \beta'_i$  (which is also optimum for  $\alpha_i, \beta_i$  )

# Perturbing for Key Weight Uniqueness (II)

- Perturb input:  $\alpha'_i = \alpha_i$  ,  $\beta'_i = \beta_i + i\epsilon$  where  $\epsilon$  is very small
  - Need to find optimum tree for  $\alpha'_i, \beta'_i$  (which is also optimum for  $\alpha_i, \beta_i$  )
- Recall that algorithm only performs additions/comparisons
  - All values are subtree costs  $\sum a_i \alpha_i + \sum b_i \beta_i$  where  $0 \leq a_i, b_i \leq 2n$  are integral

# Perturbing for Key Weight Uniqueness (II)

- Perturb input:  $\alpha'_i = \alpha_i$  ,  $\beta'_i = \beta_i + i\epsilon$  where  $\epsilon$  is very small
  - Need to find optimum tree for  $\alpha'_i, \beta'_i$  (which is also optimum for  $\alpha_i, \beta_i$ )
- Recall that algorithm only performs additions/comparisons
  - All values are subtree costs  $\sum a_i \alpha_i + \sum b_i \beta_i$  where  $0 \leq a_i, b_i \leq 2n$  are integral
- Don't actually need to know or store value of  $\epsilon$

# Perturbing for Key Weight Uniqueness (II)

- Perturb input:  $\alpha'_i = \alpha_i$  ,  $\beta'_i = \beta_i + i\epsilon$  where  $\epsilon$  is very small
  - Need to find optimum tree for  $\alpha'_i, \beta'_i$  (which is also optimum for  $\alpha_i, \beta_i$ )
- Recall that algorithm only performs additions/comparisons
  - All values are subtree costs  $\sum a_i \alpha_i + \sum b_i \beta_i$  where  $0 \leq a_i, b_i \leq 2n$  are integral
- Don't actually need to know or store value of  $\epsilon$
- Every value in algorithm is in form  $x = x_1 + x_2\epsilon$ , where  $x_2 = O(n^3)$  is an integer
  - Forget  $\epsilon$ . Store pair  $(x_1, x_2)$

# Perturbing for Key Weight Uniqueness (II)

- Perturb input:  $\alpha'_i = \alpha_i$  ,  $\beta'_i = \beta_i + i\epsilon$  where  $\epsilon$  is very small
  - Need to find optimum tree for  $\alpha'_i, \beta'_i$  (which is also optimum for  $\alpha_i, \beta_i$ )

- Don't actually need to know or store value of  $\epsilon$
- Every value in algorithm is in form  $x = x_1 + x_2\epsilon$ , where  $x_2 = O(n^3)$  is an integer
  - Forget  $\epsilon$ . Store pair  $(x_1, x_2)$
- (A) Addition is pairwise-addition
  - $(x_1, x_2) + (y_1, y_2) = (x_1 + y_1, x_2 + y_2)$
- (C) Comparison is lexicographic-comparison
  - $(x_1, x_2) < (y_1, y_2)$  iff  $x_1 < y_1$  or  $x_1 = y_1$  and  $x_2 < y_2$

# Perturbing for Key Weight Uniqueness (II)

- Perturb input:  $\alpha'_i = \alpha_i$  ,  $\beta'_i = \beta_i + i\epsilon$  where  $\epsilon$  is very small

- Every value in algorithm is in form  $x = x_1 + x_2 \epsilon$ , where  $x_2 = O(n^3)$  is an integer
  - Forget  $\epsilon$ . Store pair  $(x_1, x_2)$
- (A) Addition is pairwise-addition
  - $(x_1, x_2) + (y_1, y_2) = (x_1 + y_1, x_2 + y_2)$
- (C) Comparison is lexicographic-comparison
  - $(x_1, x_2) < (y_1, y_2)$  iff  $x_1 < y_1$  or  $x_1 = y_1$  and  $x_2 < y_2$
- Both (A) and (C) can be implemented in  $O(1)$  time without knowing  $\epsilon$
- Perturbed algorithm has same asymptotic running time as regular one

# Odds and Ends

# Odds and Ends

- Designed  $O(n^4)$  algorithm for constructing OBCSTs when  $C=\{<,=\}$  and need to report Exact Failures

# Odds and Ends

- Designed  $O(n^4)$  algorithm for constructing OBCSTs when  $C=\{<,=\}$  and need to report Exact Failures
- Strongly used assumption  $\beta_i$  are all distinct
  - Assumption can be removed using perturbation argument

# Odds and Ends

- Designed  $O(n^4)$  algorithm for constructing OBCSTs when  $C=\{<,=\}$  and need to report Exact Failures
- Strongly used assumption  $\beta_i$  are all distinct
  - Assumption can be removed using perturbation argument
- To solve problem  $C=\{<,=\}$  with Non-Exact failures
  - only need to modify initial conditions

# Odds and Ends

- Designed  $O(n^4)$  algorithm for constructing OBCSTs when  $C=\{<,=\}$  and need to report Exact Failures
- Strongly used assumption  $\beta_i$  are all distinct
  - Assumption can be removed using perturbation argument
- To solve problem  $C=\{<,=\}$  with Non-Exact failures
  - only need to modify initial conditions
- Symmetry argument gives algorithms for  $C=\{\leq, =\}$

# Odds and Ends

- Designed  $O(n^4)$  algorithm for constructing OBCSTs when  $C=\{<,=\}$  and need to report Exact Failures
- Strongly used assumption  $\beta_i$  are all distinct
  - Assumption can be removed using perturbation argument
- To solve problem  $C=\{<,=\}$  with Non-Exact failures
  - only need to modify initial conditions
- Symmetry argument gives algorithms for  $C=\{\leq, =\}$
- Algorithms for  $C=\{<, \leq, =\}$  requires only slight modifications of  $\text{SPLIT}(i,j: h)$

# Odds and Ends

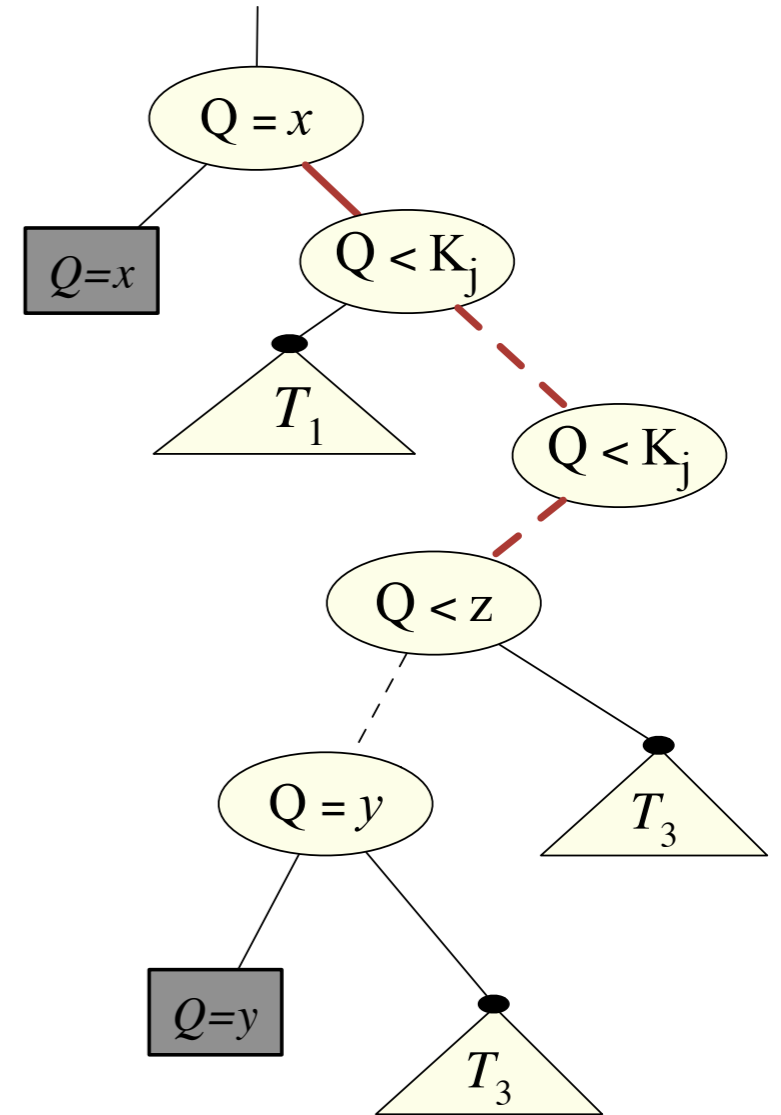

- Designed  $O(n^4)$  algorithm for constructing OBCSTs when  $C=\{<,=\}$  and need to report Exact Failures
- Strongly used assumption  $\beta_i$  are all distinct
  - Assumption can be removed using perturbation argument
- To solve problem  $C=\{<,=\}$  with Non-Exact failures
  - only need to modify initial conditions
- Symmetry argument gives algorithms for  $C=\{\leq, =\}$
- Algorithms for  $C=\{<, \leq, =\}$  requires only slight modifications of SPLIT( $i,j: h$ )
- If  $C=\{<, \leq\}$ , ranges have no holes and problem can be solved in  $O(n \log n)$  similar to Hu-Tucker

# Proof of Main Lemma

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

- $y < x$  ( $x > y$  is symmetric)

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

- $y < x$  ( $x > y$  is symmetric)
- $(Q=x)$  is above  $(Q=y)$

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

- $y < x$  ( $x > y$  is symmetric)
- $(Q=x)$  is above  $(Q=y)$
- **$\Rightarrow \beta_x < \beta_y$  will show contradiction**

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

- $y < x$  ( $x > y$  is symmetric)
- $(Q=x)$  is above  $(Q=y)$
- $\Rightarrow \beta_x < \beta_y$  will show contradiction
- $\Rightarrow \beta_x \geq \beta_y$  and Thm correct

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

- $y < x$  ( $x > y$  is symmetric)
- $(Q=x)$  is above  $(Q=y)$
- $\Rightarrow \beta_x < \beta_y$  will show contradiction
- $\Rightarrow \beta_x \geq \beta_y$  and Thm correct
- All comparisons between  $(Q=x)$  and  $(Q=y)$  are inequalities
  - otherwise  $\exists (Q=w)$  on path with either  $\beta_x < \beta_w$  or  $\beta_w < \beta_y$  and can show contradiction with  $(x,w)$  or  $(w,y)$

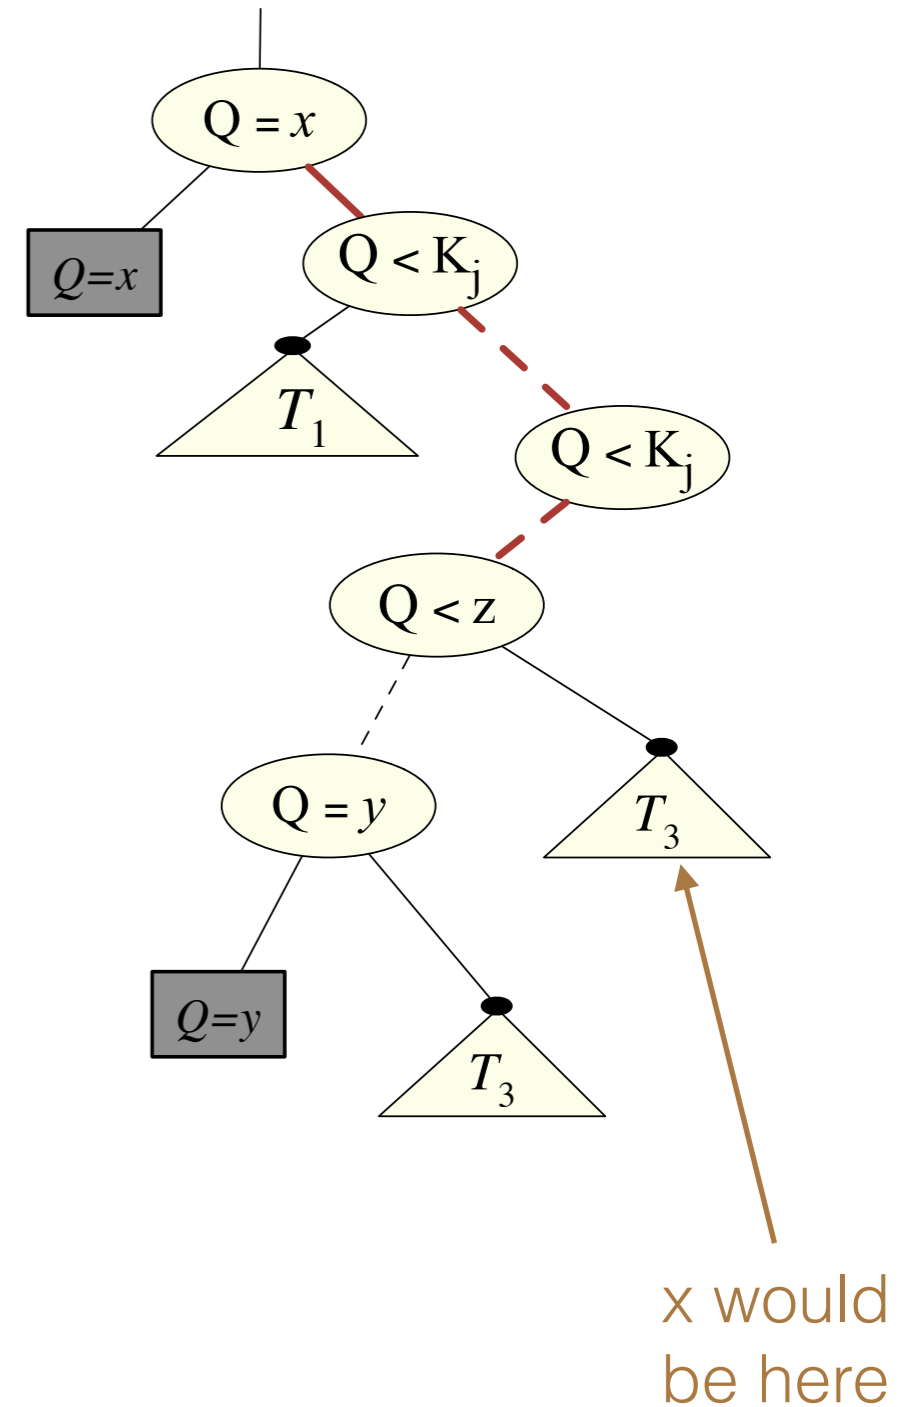

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

- $y < x$  ( $x > y$  is symmetric)
- $(Q=x)$  is above  $(Q=y)$
- $\Rightarrow \beta_x < \beta_y$  will show contradiction
- $\Rightarrow \beta_x \geq \beta_y$  and Thm correct
- All comparisons between  $(Q=x)$  and  $(Q=y)$  are inequalities
  - otherwise  $\exists (Q=w)$  on path with either  $\beta_x < \beta_w$  or  $\beta_w < \beta_y$  and can show contradiction with  $(x,w)$  or  $(w,y)$
- $x, y \in \text{Range}((Q=x))$  by definition  
 If  $x, y \in \text{Range}((Q=y))$   
 then could swap  $(Q=x)$  and  $(Q=y)$   
 to get cheaper tree.

# Proof of Main Lemma

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

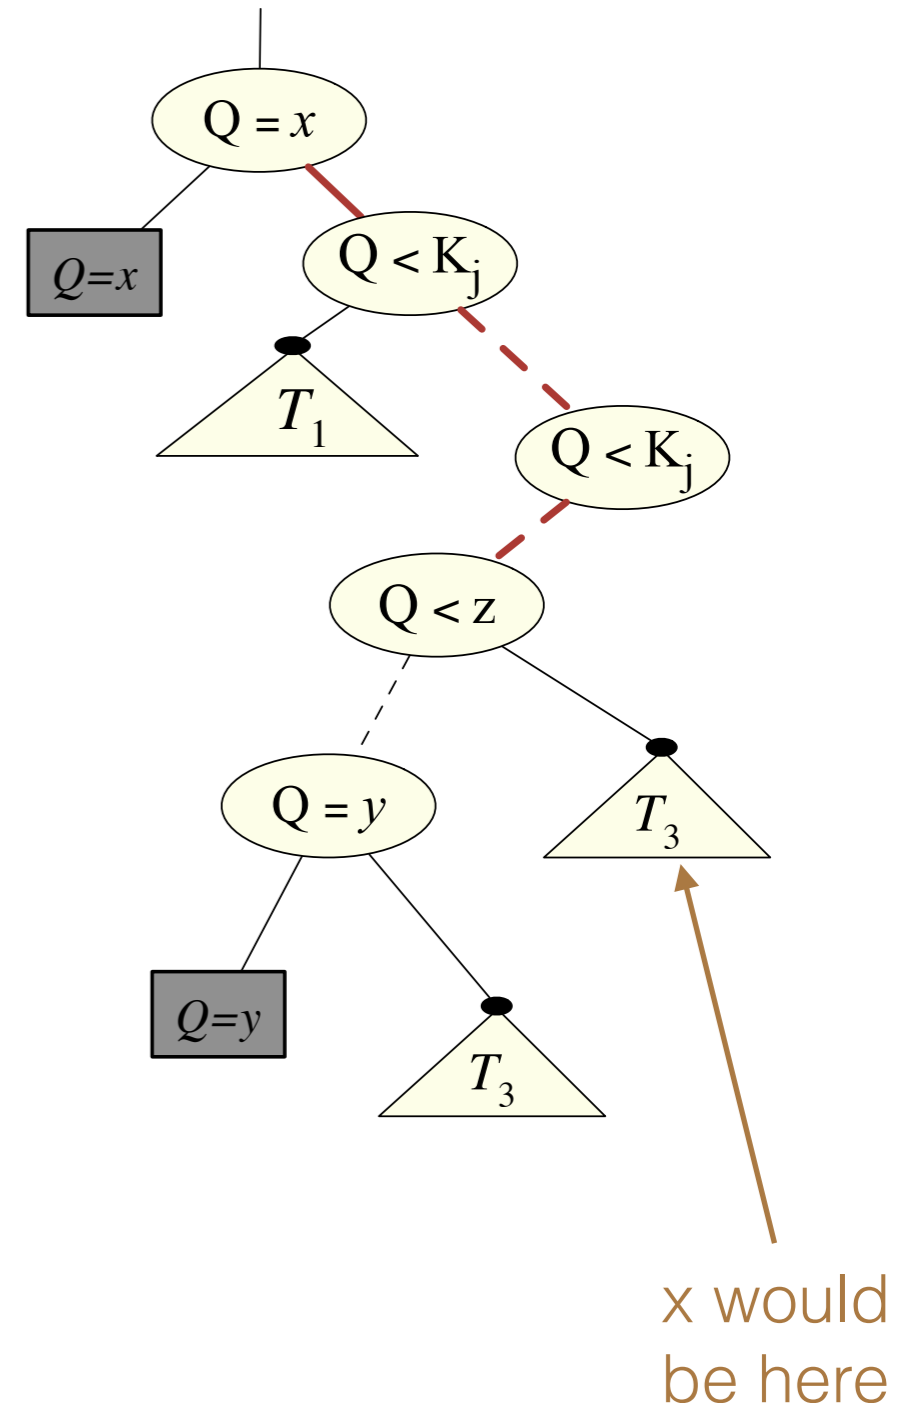

- $y < x$  ( $x > y$  is symmetric)
- $(Q=x)$  is above  $(Q=y)$
- $\Rightarrow \beta_x < \beta_y$  **will show contradiction**
- All comparisons between  $(Q=x)$  and  $(Q=y)$  are inequalities

# Proof of Main Lemma

Let  $T$  be an OBCST. Assume

- $y < x$  ( $x > y$  is symmetric)
- $(Q=x)$  is above  $(Q=y)$
- **$\Rightarrow \beta_x < \beta_y$  will show contradiction**
- All comparisons between  $(Q=x)$  and  $(Q=y)$  are inequalities
- Since  $x \notin \text{Range}((Q=y))$   
 $\Rightarrow$  Path  $(Q=x)$  to  $(Q=y)$  contains  $(Q < z)$   
s.t.  $z$ 's children's ranges are  $[i, z, h')$ ,  $[z, j, h'')$   
where  $y \in [i, z)$  and  $x \in [z, j)$ .  
 $z$  is called *splitter*.
- $P'$  is (red) path from  $(Q=x)$  to  $(Q=y)$

# Proof of Main Lemma

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$
- Proof will be case analysis of structure of  $P'$
- For every  $P'$ , will show can build cheaper OBCST  $T'$  contradicting optimality of  $T$

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$
- Proof will be case analysis of structure of  $P'$
- For every  $P'$ , will show can build cheaper OBCST  $T'$  contradicting optimality of  $T$

## Case 1: $P'$ is one edge

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$
- Proof will be case analysis of structure of  $P'$
- For every  $P'$ , will show can build cheaper OBCST  $T'$  contradicting optimality of  $T$

## Case 1: $P'$ is one edge

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$
- Proof will be case analysis of structure of  $P'$
- For every  $P'$ , will show can build cheaper OBCST  $T'$  contradicting optimality of  $T$

## Case 1: $P'$ is one edge

$y \in A \Rightarrow \text{Weight}(A) \geq \beta_y > \beta_x$

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$
- Proof will be case analysis of structure of  $P'$
- For every  $P'$ , will show can build cheaper OBCST  $T'$  contradicting optimality of  $T$

## Case 1: $P'$ is one edge

$y \in A \Rightarrow \text{Weight}(A) \geq \beta_y > \beta_x$

$\Rightarrow$  replacing left subtree by right subtree in  $T$  yields new BCST  $T'$  with lower cost than  $T$ , contradicting  $T$  being OBCST

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$

## Case 2: $P'$ is two edges $\neq \leftarrow$

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$

## Case 2: $P'$ is two edges $\neq$

$y \in A \Rightarrow \text{Weight}(A) \geq \beta_y > \beta_x$

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$

## Case 2: $P'$ is two edges $\neq$

$$y \in A \Rightarrow \text{Weight}(A) \geq \beta_y > \beta_x$$

$\Rightarrow$  again replacing left tree by right tree in  $T$  yields new BCST  $T'$  with lower cost than  $T$ , contradicting  $T$  being OBCST

# Proof of Main Lemma

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$
- Proof will be case analysis of structure of  $P'$

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$
- Proof will be case analysis of structure of  $P'$
  
- Already saw first two cases of  $P'$ 
  - Showed for each that assumptions allow replacing subtree rooted at  $(Q=x)$  with cheaper subtree for some range.  
Replacement leads to cheaper BCST, contradicting optimality of  $T$

# Proof of Main Lemma

- $P$  is path in  $T$  from  $(Q=x)$  to  $(Q=y)$ .  $y < x$ .  $z$  is  $x$ - $y$  splitter on  $P$
- $P'$  is path from  $(Q=x)$  to  $(Q=z)$
- Proof will be case analysis of structure of  $P'$
  
- Already saw first two cases of  $P'$ 
  - Showed for each that assumptions allow replacing subtree rooted at  $(Q=x)$  with cheaper subtree for some range.  
Replacement leads to cheaper BCST, contradicting optimality of  $T$
  
- The full proof splits  $P'$  into 7 cases.
  - For each, can show replacement with cheaper subtree, contradicting optimality of  $T$ .

# Extensions & Open Problems

- If the  $\beta_i, \alpha_i$  are probabilities (sum to 1) can show an  $O(n)$  algorithm that constructs BCST within **additive error 3 of optimal** for Exact Failure Case
  - Modification of similar algorithm for Hu-Tucker case.
- $O(n^4)$  is quite high for worst case.
  - Can we do better?
