Introduction

The **Amazon Discussions Feedback Forum (Amazon Forum)** is a platform for discussing matters relating to Amazon. With millions of registered users, this forum has three obvious problems:

1. Users can't quickly identify the **posts of interest**.
2. Users can't quickly identify the **current hot topics**.
3. Amazon can't place **effective advertisements** there.

Objective

To solve the three problems, we developed a website called "**Amazon Discussions Feedback Forum topic browser**" so that users can browse this forum by topics, and receive relevant advertisements.

To do so, we:

- **Fetch** posts from the Amazon forum.
- **Detect** hidden topics from the posts using latent Dirichlet allocation (LDA), a topic model algorithm.
- **Link** each post to corresponding topics.
- **Display** the list of topics on a website.
- **Provide relevant advertisements** to each topic.

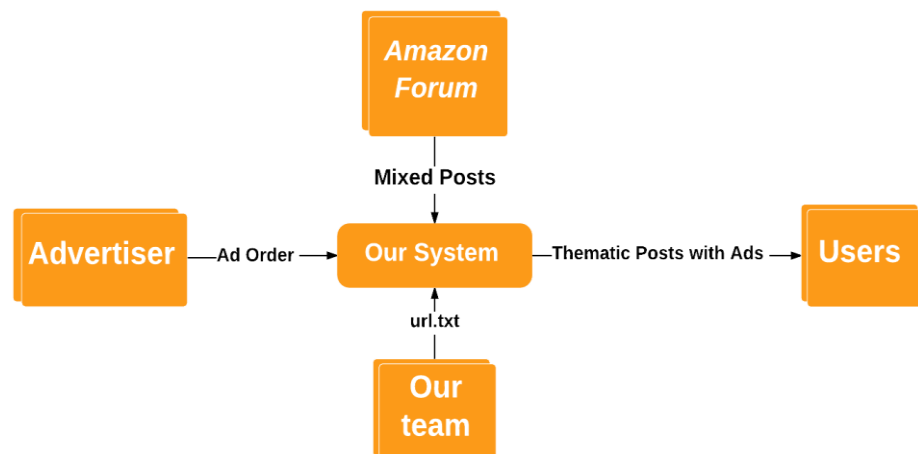

Figure 2: Showing the relationships of our system with relevant stakeholders

User interface

In the homepage, users can view the detected topics. They can then **click on a topic** to view the posts related to it.

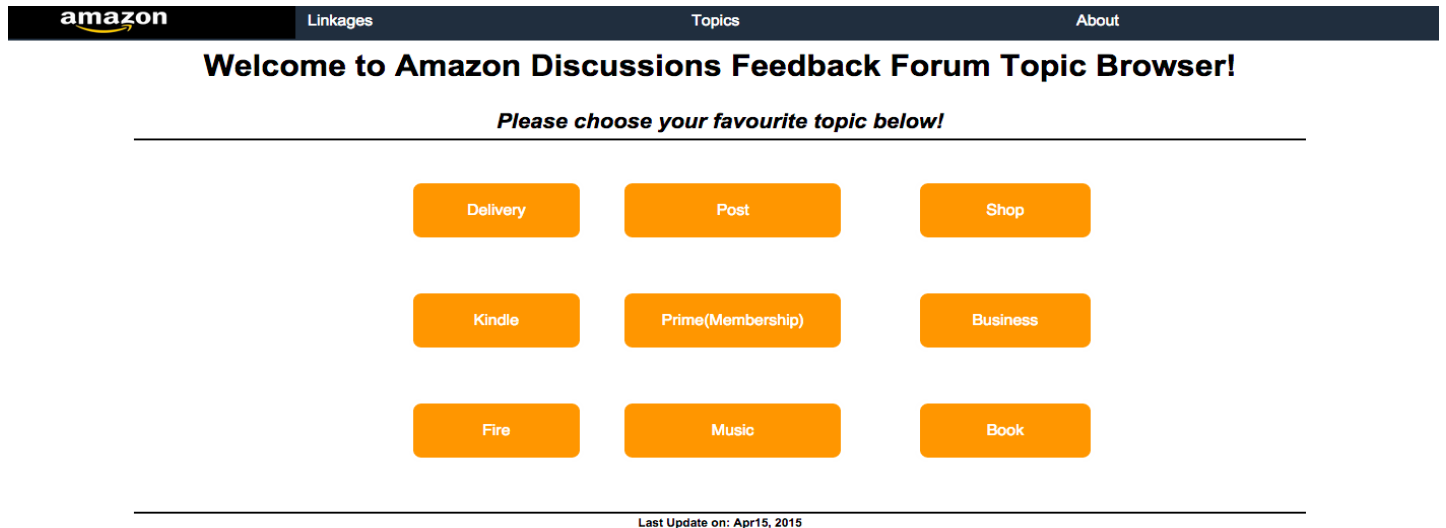

Figure 3: Homepage of our homepage

When users click on "Delivery", the following webpage is shown. The middle column shows the posts related to "Delivery". A **navigation bar** (left) and a relevant **advertisement** (right) are also displayed.

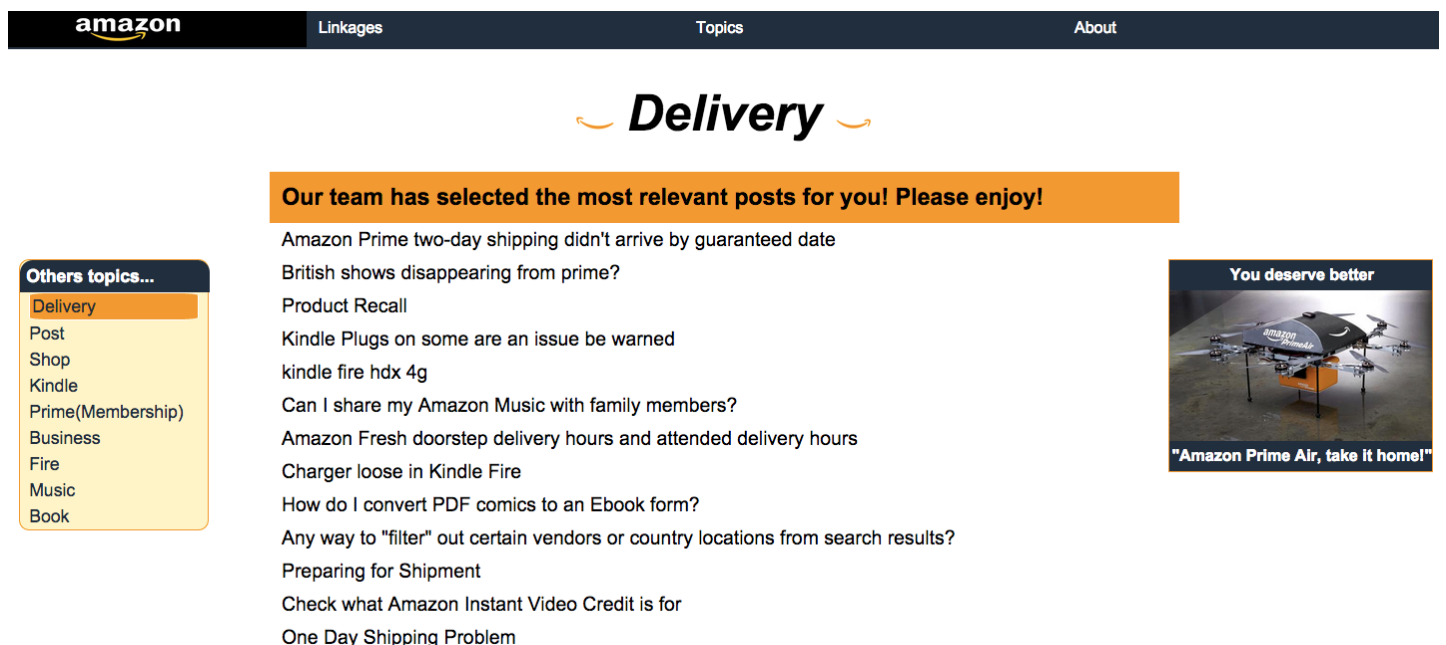

Figure 4: "Delivery" page with a related ad

Principle

To **automatically detect hidden topics** from the posts, we used a well-known probabilistic topic modeling algorithm – latent Dirichlet allocation (**LDA**), which is particularly suitable for processing text data.

In LDA, we let $\{\beta_1, \beta_2, \dots, \beta_k\}$ be the hidden topics, and assume that each word is drawn from the identical vocabulary set $\{1, \dots, V\}$. A document is represented by a sequence of words $\{W_1, W_2, \dots, W_n\}$. Each word is generated by one topic $z = \{1, \dots, k\}$. A Dirichlet prior $Dir(\alpha)$ is introduced to the K-dimensional document-topic distribution $\theta^{(d)}$. The following is the generative process for a N-word document d :

- Choose topic proportions $\theta \sim Dir(\alpha)$
- For each word W_n :
 1. Choose a topic assignment $z_n \sim Mult(\theta)$
 2. Choose a word W_n from $p(W_n | z_n, \beta)$

The relationship among different parameters are illustrated below:

Summary

In this project we developed a topic-based browser for the forum, with an aim to help save the users' precious time.

We have:

- **Fetches** 500 posts with 4394 replies.
- **Detected** 9 thematic topics.
- **Established** the linkages between the topics and the relevant posts.
- **Displayed** the posts in a **user-friendly** website.
- **Placed relevant advertisements** with a personalized message.
